| SITE/PERIOD/SAMPLER/ CONFIGURATION | | | | SUMMARY OF FINDINGS |
|---|--------------------------|---|------------------------------------|---|
| CONTINUOUS SAMPLER | FLOW RATE (L/min) | DENUDER | ANALYSIS METHOD^b | <p>(RSD = 13%) was similar to that for NO₃ instruments. Filter sample variability was low (RSD = 8%) indicating more uniformity among samplers.</p> <p>The ECN and TT instruments were within 15%, PILS-IC was within 20% and ADI-S was within 26% of filter RR.</p> |
| ADI-S | 2.7 | Activated Carbon | SO ₂ , UV Fluorescence | |
| PILS-IC | 5 | Two URG annular glass denuders in series containing citric acid & CaCO ₃ | IC | |
| ECN | 16.7 | Rotating annular wet denuder system | IC | |
| TT | 5 | Wet parallel plate denuder | IC | |
| PITTSBURGH SUPERSITE, PA; 07/01/01 to 08/01/02 6km east of downtown in a park on the top of a hill | | | | Cabada et al.,¹⁸; Takahama et al.,¹¹⁶ MOUDI SO ₄ ²⁻ 0.80 CMU; R ₂ = 0.95; Summer MOUDI SO ₄ ²⁻ 0.97 CMU; R ₂ = 0.48; winter Wittig et al.⁸⁵ Avg conversion efficiency to SO ₂ (tested using ammonium sulfate [(NH ₄) ₂ SO ₄] solution) was 0.65 ± 0.07. Gas analyzer efficiency was stable at 0.99 ± 0.06. Corrections were made for instrument offset, software calculation error, conversion efficiency, gas analyzer efficiency, vacuum drift, and sample flow drift. The overall correction was, on avg, -1% and ranged from -90% to 100% for individual samples. Data Recovery > 90%. Data loss was associated with vacuum pump failures or excessive flash strip breakage. R&P-8400S (SO ₄ ²⁻) = 0.71 CMU + 0.42 µg/m ³ ; R ₂ = 0.83 Underestimation is attributed to incomplete particle collection or incomplete conversion of various forms of SO ₄ ²⁻ . Used co-located filter measurements for final calibration. |

| NEW YORK SUPERSITE, NY; 06/29/01 to 08/05/01 and 07/09/02 to 08/07/02 Urban site located at Queens College, NY, about 14 km west of Manhattan, within 2 km of freeways, and within 12 km of international airports. Rural site located at Whiteface mountain, 600m above sea level, in a clearing surrounded by deciduous and evergreen trees and no major cities within 20 km of the site. | | | | Drewnick et al.²¹; Hogrefe et al.²⁰ Data completeness: 89 - 93% for R&P-8400S, 94 - 98% for AMS, 81-98% for CASM, and 65-70% for PILS-IC. The urban site data showed good correlations (R ₂ = 0.87 to 0.94) with slopes ranging from 0.97 to 1.01. At the rural site, the variability was large (R ₂ = 0.73 to 0.91) with slopes ranging from 0.76 to 1.32. SO ₄ from PILS-IC was overestimated by |
| SAMPLER | FLOW RATE (L/MIN) | FILTER TYPE^a | DENUDER^b | |
| R&P-2300 | 10 | Nylon (n/a) | Na ₂ CO ₃ | |
| SCS | 42 | Zefluor (n/a) | None | |

| SITE/PERIOD/SAMPLER/ CONFIGURATION | | | | SUMMARY OF FINDINGS |
|--|--------------------------|--|------------------------------------|---|
| TEOM-ACCU | 16.7 | Zefluor (n/a) | None | ~ 25% when compared to the AMS at the rural site. |
| CONTINUOUS SAMPLER | FLOW RATE (L/min) | DENUDER | ANALYSIS METHOD^b | Filter samples were within 5% of each other, except for comparison of ACCU with R&P-2300 at the rural site, with high correlations ($R^2 = 0.97$ to 1.0). ACCU underestimated SO_4^{2-} by ~ 15%. |
| R&P-8400S | 5 | Activated Carbon | SO_2 UV Fluorescence | Continuous versus six-h SCS filter comparisons showed high R^2 (0.91 to 0.95) at the urban site. |
| PILS-IC | 5 | Na_2CO_3 and Citric acid | IC | Continuous instruments consistently measured lower SO_4^{2-} concentrations compared to the SCS filter measurements (slopes 0.68 to 0.73) |
| AMS | 0.1 | None | Mass Spectrometry | On avg, 85% of the filter-based SO_4^{2-} was measured by the continuous instruments with consistent relationships. At the rural site, PILS-IC overestimated SO_4^{2-} concentrations (slopes 1.11 to 1.15), AMS and R&P-8400S showed slopes of 0.71-0.74 against SCS and ACCU, while it ranged from 0.53- 0.68 against R&P-2300. |
| CASM | 5 | Na_2CO_3 and Carbon and a Nafion dryer | SO_2 UV Fluorescence | Error estimates: Sampling losses: 2-3% for AMS and PILS-IC, 5-10% for R&P-8400S and none for CASM. Continuous instruments probably experienced more inlet transport losses (~ 25%) than filter samplers due to longer inlet lines. Small (< 2%) positive artifact was found in filters. |
| NEWYORK SUPERSITE, NY; 10/01 to 07/05 (urban), 07/02 to 07/05 (rural) | | | | Rattigan et al.⁸⁴ |
| Urban site located at a school in South Bronx, NY in a residential area, within a few kilometers from major highways and a freight yard (experiencing significant truck traffic). Rural site located at Whiteface mountain, 600m above sea level, in a clearing surrounded by deciduous and evergreen trees and no major cities within 20 km of the site. The study by Schwab et al. ⁸⁹ was based at a rural site located at Pinnacle State Park surrounded by golf course, picnic areas and undeveloped forest lands and no major cities within 15 km. | | | | Data capture was above 85%. Data loss was primarily due to frequent flash strip failures, every 2 weeks and without warning. Data were adjusted for span and zero drifts, measured conversion efficiency, flow drift, and blanks. |
| INTEGRATED SAMPLER | FLOW RATE (L/MIN) | FILTER TYPE^a | DENUDER^b | Calibrations used aqueous standards of $(NH_4)_2SO_4$ and oxalic acid solution in 1: 4 ratio. Lower fractions of oxalic acid showed lower conversion efficiencies. |
| R&P-2300 | 10 | Nylon (n/a) | Na_2CO_3 | Urban South Bronx site: $R\&P-8400S = 0.82\ TEOM-ACCU + 1.15$; $R^2 = 0.84$; $n = 513$ |
| TEOM-ACCU | 16.7 | Zefluor | None | $R\&P-8400S = 0.74\ R\&P-2300 + 1.14$; $R^2 = 0.81$; $n = 322$ |
| CONTINUOUS SAMPLER | FLOW RATE (L/min) | DENUDER | ANALYSIS METHOD^b | Rural Whiteface mountain: $R\&P-8400S = 0.75\ TEOM-ACCU + 0.22$; $R^2 = 0.95$; $n = 207$ $R\&P-8400S = 0.78\ R\&P-2300 + 0.17$; $R^2 = 0.85$; $n = 198$ |
| R&P-8400S | 5 | Activated Carbon | SO_2 pulsed fluorescence | Required weekly or biweekly maintenance by trained personnel |
| TE-5020 (07/14/04 to 11/01/04) | 5 | Na_2CO_3 | SO_2 pulsed fluorescence | Schwab et al.⁸⁹ $TE-5020 = 0.78\ ACCU - 0.2$; $R^2 = 0.94$ Similar studies at St. Louis, MO, show slopes near unity. This suggests that the instrument is sensitive to aerosol composition. Low maintenance and calibration requirements for TE-5020 compared to PILS-IC and R&P-8400S. |

Table A-15. Summary of PM_{2.5} carbon measurement comparisons.

| SITE/PERIOD/SAMPLER/ CONFIGURATION | | | | | SUMMARY OF FINDINGS |
|--|-------------------|--------------------------|----------------------|------------------------------|--|
| ATLANTA SUPERSITE, GA: 08/03/99 to 09/01/99 4 km NW of downtown, within 200 m of a bus maintenance yard and several warehouse facilities, representative of a mixed commercial-residential neighborhood. | | | | | Solomon et al. ¹⁷ Organic Carbon (OC); PM _{2.5} OC from each sampler was compared to the all-sampler avg, called the relative reference (RR) value. The samplers agreed to within 20 to 50% of RR. Only front filter OC is reported without artifact correction. Denuded samplers showed lower OC (20 to 35%) than RR, while non-denuded sampler OC was higher (5 to 35%). Among non-denuded samplers, as filter face velocity decreased, OC increased, with the exception of R&P-2300. |
| SAMPLER | FLOW RATE (L/MIN) | FILTER TYPE ^a | DENUDER ^b | ANALYSIS METHOD ^c | |
| R&P-2000 FRM | 16.7 | Quartz (P) | None | NIOSH 5040-TOT | |
| RAAS-400 | 24 | Quartz (P) | None | NIOSH 5040-TOT | |
| SASS | 6.7 | Quartz (P)- Quartz (P) | None | NIOSH 5040-TOT | |
| MASS-450 | 16.7 | Quartz (P) | None | NIOSH 5040-TOT | |

| SITE/PERIOD/SAMPLER/ CONFIGURATION | | | | | SUMMARY OF FINDINGS |
|--|-------------------|---------------------------------|---|---|---|
| R&P-2300 | 10 | Quartz (P)- Quartz (P) | None | NIOSH 5040-TOT | OC positive artifacts ranged from 2 to 4 $\mu\text{g}/\text{m}^3$ EC: |
| VAPS | 15 | Quartz (P) | XAD-4 | NIOSH 5040-TOT | PM _{2.5} EC from each sampler was compared to the all-sampler avg, called the relative reference (RR) value. The samplers agreed to within 20 to 200% of RR. |
| URG-PCM | 16.7 | Quartz (P)- Quartz (P) | XAD-4 | Front: NIOSH 5040-TOT; Backup: custom-TOT ^d | TOT samples showed less EC than RR by 15 to 30%, while TOR samples showed more EC than RR by 40 to 90%. PCBOSS (BYU) > RR value by 140%. EC by TOR is ~ twice EC by TOT. |
| ARA-PCM | 16.7 | Quartz (n/a)- Quartz (n/a) | CIF | IMPROVE_TOR | Major difference in EC is due to the carbon analysis protocol and optical monitoring correction (i.e., transmittance, reflectance). |
| PC-BOSS (TVA) | 150 | Quartz (P)- CIF (n/a) | CIF | Front: IMPROVE_TOR; Backup: TPV | Lim et al. (2003) |
| PC-BOSS (BYU) | 150 | Quartz (P)-CIF (S) | CIF | TPB | TC concentrations measured by the RU-OGI and R&P-5400 correlated reasonably well ($R^2 = 0.83$), with a slope of 0.96. The ratio of the mean RU-OGI to mean R&P-5400 TC was 1.02. |
| MOUDI-100 | 30 | Al Foil-Quartz (n/a) | None | Custom-TOR to suit Al ^c | R&P-5400 OC was 8% lower than the RU-OGI ($R^2 = 0.73$), while the R&P-5400 EC was 20% higher than RU-OGI ($R^2 = 0.74$). |
| CONTINUOUS SAMPLER | FLOW RATE (L/min) | DENUDER | OC | EC | COMMENTS |
| ADI-C | 2.7 | Activated Carbon | Not known | n/a | Part of SO ₂ ² instrument w/CO ₂ non-dispersive infrared (NDIR) analyzer; data corrected for avg field blank; OC = 2 oxidized OC |
| RU-OGI | 16.1 | None | 700 in He | 850 in 2% O ₂ | TOT; Dynamic blank for adsorption correction |
| R&P-5400 | 16.7 | None | 275 in air | 750 in air | No pyrolysis correction |
| PSAP | 1.26 | None | | b _{abs} @ 565 nm | 10m ² /g factor |
| AE-16 | 4 | None | | b _{abs} @ 880 nm | 12.6 m ² /g factor |
| PITTSBURGH SUPERSITE, PA; 06/01/01 to 07/31/02 Six km east of downtown in a park on the top of a hill. | | | | | Subramanian et al. ¹¹⁹ |
| SAMPLER | FLOW | FILTER TYPE / PACK ^a | DENUDER | ANALYSIS METHOD ^c | |
| CMU Custom-1 | 16.7 | <i>Non-denuded sample</i> | Teflon (P/W)- Quartz (P) (QBT) | None | NIOSH 5040-TOT |
| | 16.7 | <i>Non-denuded sample</i> | Quartz (P)-Quartz (P) (QBQ) | None | NIOSH 5040-TOT |
| CMU Custom-2 | 16.7 | <i>Denuded sample</i> | Denuder-Quartz (P)-CIG (S) | Activated Carbon | NIOSH 5040-TOT |
| | 16.7 | <i>Dynamic blank (DYN)</i> | Teflon (P/W)- Denuder-Quartz (P)-CIG (S) | Activated Carbon | NIOSH 5040-TOT |

| SITE/PERIOD/SAMPLER/ CONFIGURATION | | | | | SUMMARY OF FINDINGS |
|--|-------------------------|---------------------------------------|----------------------------------|---|--|
| 16.7 | Non-denuded blank (UDB) | Teflon (P/W)-Quartz (P)-CIG (S) | None | NIOSH 5040-TOT | <p>QBT over-corrected the positive artifact by 20%. OC volatilization from the front Teflon filter that subsequently-adsorbed on the back-up quartz filter, resulted in an overestimation of the positive artifact.</p> <p>Non-denuded QBQ provided a more representative estimate of the positive artifact on the non-denuded front quartz filter for 24-h samples. However, it was not suitable for 4-6 h samples, because the filters were not in equilibrium with the air stream.</p> <p>Positive artifact dominated when sampling with a non-denuded quartz filter.</p> <p>Comparison of 24-h avg non-denuded front quartz OC versus denuded POC over the year showed an intercept of $0.53 \mu\text{g}/\text{m}^3$, indicative of a positive artifact on quartz filter samples.</p> <p>The artifacts were higher in summer on an absolute basis; however, they showed no seasonal variation when expressed as a fraction of POC.</p> |
| ST. LOUIS SUPERSITE, IL, MO; 01/01/02 to 12/31/02 Three km east of St. Louis, MO City center, also impacted by industrial sources, and located in a mixed residential light commercial neighborhood. | | | | | Bae et al. ^{93, 96} Denuder breakthrough was $0.17 \pm 0.15 \mu\text{g}/\text{m}^3$, and constituted less than 5% of annual avg OC concentration. Non-denuded OC = $(1.06 \pm 0.02) \times \text{denuded OC} + (0.34 \pm 0.10)$ Equivalence of OC intercept and denuder breakthrough implies that the low-level artifact is caused by denuder breakthrough. Non-denuded EC = $(1.04 \pm 0.03) \times \text{denuded EC} + (0.07 \pm 0.03)$, indicating negligible EC artifact. Results suggested higher summer-time OC artifact, on an absolute basis. Comparison of continuous Sunset TC and OC with 24-h filter samples showed good correlations (R2) of 0.89 and 0.90, respectively. Continuous Sunset TC in $\mu\text{g}/\text{m}^3$ = $(0.97 \pm 0.02) \times \text{filter TC} + (0.83 \pm 0.11)$, indicating comparability with the filter measurements. Continuous Sunset OC = $(0.93 \pm 0.02) \times \text{filter OC} + (0.94 \pm 0.09)$ Positive intercept was interpreted to be a blank correction for the continuous measurements. EC comparison was poor with large scatter in data (R2 = 0.60), probably due to low EC concentrations (avg = $0.70 \mu\text{g}/\text{m}^3$), close to the detection limit ($0.5 \mu\text{g}/\text{m}^3$). |

Table A-16. Summary of particle mass spectrometer measurement comparisons.

| Spectrometer | Inlet Characteristics ^a (Flow Rate [L/Min] Size Inlet Dryer Aerodynamic Diameter, μm Particle Sizing Method) | Volatilization/Ionization Method ^a | Hit Rates ^b | Mass Spectrometer ^c | Particle Analysis/Classification | Other |
|--------------|--|---|--------------------------------------|---|--|--|
| PALMS | n/a PM _{2.5} cyclone Nafion (17 days) / None (4 days) 0.35 - 2.5 Light scattering | LDI, ArF 193 nm 2x109 to 5x109 W/cm2 | 14 to 100%, overall 87% | Single TOF reflectron; ion polarity needs to be pre-selected | Peak ID/regression tree analysis | Pure sulfuric acid (H ₂ SO ₄), (NH ₄) ₂ SO ₄ , and water (H ₂ O) have relatively high ionization thresholds (i.e. difficult to ionize). Fraction of molecules ionized in the particles is on the order of 10 ⁻⁵ to 10 ⁻⁶ . |
| ATOFMS | 1 None None 02 - 2.5 Aerosol TOF | LDI, Nd: YAG 266 nm laser ~ 1x108 W/cm2 | 25-30%, occasionally as low as 5% | Dual TOF reflectron; Detects both positive and negative ions | Aerosol TOF | |
| RSMS-II | n/a None Nafion 0.015 - 1.3 Aerodynamic focusing Need to pre-select sizes to be analyzed | LDI, Arf laser, 193 nm 1x108 to 2x108 W/cm2 | n/a | Single linear TOF; ion polarity needs to be pre-selected | Peak ID/artificial neural network | |
| AMS | n/a PM _{2.5} cyclone None 0.05 - 2.5 Aerosol TOF | T ~ 550 °C/ EI | n/a | Quadrupole; Mass weighted size distributions on pre-selected positive ions only. | ID using standard EI ionization databases | Does not detect/analyze highly refractory materials such as metals, sea salt, soot etc. Fraction of molecules ionized in the particles is on the order of 10 ⁻⁶ to 10 ⁻⁷ |

Middlebrook et al. ¹³¹; **Wenzel et al.** ¹³²; **Jimenez et al.** ¹³³

Particle sizing is approximate in PALMS, while ATOFMS, RSMS-II and AMS provide relatively accurate particle sizing.

Particle transmission in AMS is ~ 100% (i.e., it uses all particles in the sampled air) between 60 and 600 nm, while that for PALMS, ATOFMS and RSMS-II range from 10⁻⁶ for submicron particles to 2% for supermicron (> 0.8 μm) particles.

AMS has fewer matrix effects (due to separate volatilization and ionization steps) compared to single-step LDI instruments.

While four major particle classifications (organic/ SO₄²⁻, sodium/potassium sulfate, soot/hydrocarbon and mineral) were observed by all three laser instruments, they differed in the classification frequencies. Differences in frequencies that are detected and grouped are related to the differences in the laser ionization conditions (e.g., wavelength), particle transmission, sizing method and the way the spectra were classified.

Shorter ionization wavelengths are able to produce ions more easily than longer ones.

Low hit rates in ATOFMS corresponded to periods of high SO₄²⁻ concentrations. Low hit rates in PALMS were related to a variety of factors including high SO₄²⁻ concentrations, differing laser fluence and laser position relative to particle beam. Use of a dryer in PALMS enhanced ionization of particles that were difficult to ionize at high ambient RH.

The RSMS-II and ATOFMS were less sensitive to SO₄²⁻ and hence may have fewer organic/SO₄²⁻ particles (i.e., underestimate SO₄²⁻, pure sulfuric acid etc.).

The PALMS, ATOFMS and RSMS (laser based instruments) are qualitative, while the AMS can be quantitative. The relative ratio of ion intensities from the laser instruments, however, may be indicative of relative concentrations, thus giving semi-quantitative information.

Comparison of the ratio of NO₃ to SO₄ peaks with the results from the semi continuous instruments showed better correlation with the AMS (R₂ = 0.93) than PALMS (R₂ = 0.65 for non-dry particles to 0.70 for dry particles). While reasonable correlations between the PALMS and the composite semi-continuous data indicate the possibility for calibration of laser-based data for certain ions, the calibration factors may vary depending on the particle matrix, water content and laser ionization parameters, and averaging the spectra according to these factors may minimize these effects.

Comparison of AMS SO₄ with PILS SO₄ showed good correlation (R₂ = 0.79), and the data uniformly scattered around a 1:1 line. NO₃ comparison was poor (R₂ = 0.49) because of the low signal to noise ratio at low concentrations

The continuum between particle classifications indicates that the particles were not adequately represented by non-overlapping classifications.

¹³⁶ Zhang et al. ; ¹³⁷ Bein et al.

The AMS observed 75% of the SO_4^{2-} measured by R&P-8400S ($R^2 = 0.69$).

Collection efficiency (CE) of 0.5 used for SO_4^{2-} , NO_3 and NH_4^+ and 0.7 for organics to correct mass concentrations for incomplete detection. Use of a constant CE irrespective of size and shape may overestimate accumulation mode (mostly, oxygenated) organics (true CE ~ 0.5) and underestimate smaller mode (primary) organics (true CE ~ 1.0).

Comparison of AMS organics (organic matter, OM) with OC measured by a continuous Sunset OCEC instrument showed good correlation ($R^2 = 0.88$) with a slope of 1.69. A 24-h avg comparison, showed a slope of 1.45. These values are in the typical range of 1.2 to 2.0 for OM/OC ratios.

AMS could be used along with the SMPS to estimate particle density. The AMS did not always agree with SMPS, probably due to non-spherical particles (irregular) such as soot from fresh traffic emissions, whose mass may be overestimated by the SMPS.

Comparison of AMS mass with the MOUDI, showed differences for aerodynamic diameters $> 600 \text{ nm}$, probably due to the AMS transmission being less than unity for particles larger than 600 nm.

For RSMS-III, 54% of the detected particles were assigned to one class (carbonaceous ammonium nitrate). This class was preferentially detected during the colder months and was detected from many different wind directions.

The next largest RSMS-III class was EC/OC/K class at 11%, and is believed to be from biomass burning.

An unidentified organic carbon RSMS-III class (3.3% of all detected particles) was seen to be highly dependent on wind direction dependence and was primarily detected during August and September of 2002. These particles likely originated from a landfill.

NEW YORK SUPERSITE; 06/30/01 to 08/05/01 (urban); 07/09/02 to 08/07/02: (rural)

Urban Site: Queens College, Queens, New York, located at the edge of a parking lot and within 1 km from expressways and highways in New York City Metropolitan area.

Rural Site: Whiteface Mountain, New York, located in a cleared area surrounded by mix of deciduous and evergreen trees, $\sim 2 \text{ km}$ away from the closest highway with no major cities within 20 km.

| Spectrometer | Inlet Characteristics ^a (Flow Rate [L/Min] Size Inlet Dryer Aerodynamic Diameter, μm Particle Sizing Method) | Volatilization/Ionization Method ^a | Hit Rates ^b | Mass Spectrometer ^c | Particle Analysis/Classification | Other |
|--|---|---|------------------------|--------------------------------|----------------------------------|---|
| Drewnick et al. ^{138, 139} , Hogrefe et al. ²⁰ Transport losses were 1.3% on avg. Inlet losses (at the inlet of AMS) were 1.9%, on avg, ranging from 11% for a 20 nm particle to 9% for a 2.5 μm particle, with a minimum of 0.7% for a 350 nm particle Overall measurement uncertainty of particle diameter was $\sim 11\%$. The AMS was reliable with proper calibration, care, and maintenance. Valid 10 min averages were obtained for all components more than 93% of the time. The mass to charge ratios (m/z) of fragments from different components may overlap (e.g., NH^+ , a fragment of NH_4^+ and CH_3^+ , a fragment of organic species, have m/z = 15) resulting in an interference (called as isobaric interference) Interfering signals were not used to calculate concentrations. This loss in concentration was adjusted by applying a correction factor determined from laboratory studies. Typical interferences were from fragments of organic species, water and oxygen. With adjustments, the SO_4^{2-} , NO_3^- , and ammonium concentrations measured by the AMS were consistently lower than that measured by other co-located instruments, probably due to incomplete focusing of the $(\text{NH}_4)_2\text{SO}_4$ and NH_4NO_3 particles by the aerodynamic lens. At the urban site, AMS NO_3 was within 10% of the filter NO_3 concentration. At the rural site, it had a slope of 0.51 and R2 of 0.46. AMS SO_4 showed good agreement with R&P-8400S at both the rural and urban locations (R2 = 0.89 to 0.92, slope = 0.99, n = 407 to 695) and was within 70 to 85% of filter SO_4^{2-} concentration. Comparison of the total non-refractory mass measured by the AMS with the $\text{PM}_{2.5}$ TEOM mass (operated at 50 °C or with dryer) at the urban location, showed good correlation (R2 = 0.91) with near zero intercept (0.22 $\mu\text{g}/\text{m}^3$). On avg, the AMS observed 64% of the mass measured by the TEOM. The unexplained mass (36%) was attributed to transport losses, transmission and optical losses, and refractory components in the aerosol sample (e.g., metals, EC). The mass closure was within the estimated uncertainty of the AMS mass measurements (5 to 10%). | | | | | | |
| BALTIMORE SUPERSITE, MD; 04/01/02 to 11/30/02 East of downtown in an urban residential area. Within 91 m of a bus maintenance facility. | | | | | | |

This loss in concentration was adjusted by applying a correction factor determined from laboratory studies. | | | | | | |
| Typical interferences were from fragments of organic species, water and oxygen. | | | | | | |
| With adjustments, the SO ₄ ²⁻ , NO ₃ , and ammonium concentrations measured by the AMS were consistently lower than that measured by other co-located instruments, probably due to incomplete focusing of the (NH ₄) ₂ SO ₄ and NH ₄ NO ₃ particles by the aerodynamic lens. | | | | | | |
| At the urban site, AMS NO ₃ was within 10% of the filter NO ₃ concentration. At the rural site, it had a slope of 0.51 and R2 of 0.46. | | | | | | |
| AMS SO ₄ showed good agreement with R&P-8400S at both the rural and urban locations (R2 = 0.89 to 0.92, slope = 0.99, n = 407 to 695) and was within 70 to 85% of filter SO ₄ ²⁻ concentration. | | | | | | |
| Comparison of the total non-refractory mass measured by the AMS with the PM _{2.5} TEOM mass (operated at 50 °C or with dryer) at the urban location, showed good correlation (R2 = 0.91) with near zero intercept (0.22 μ g/m ³). On avg, the AMS observed 64% of the mass measured by the TEOM. | | | | | | |
| The unexplained mass (36%) was attributed to transport losses, transmission and optical losses, and refractory components in the aerosol sample (e.g., metals, EC). The mass closure was within the estimated uncertainty of the AMS mass measurements (5 to 10%). | | | | | | |
| BALTIMORE SUPERSITE, MD; 04/01/02 to 11/30/02 | | | | | | |
| East of downtown in an urban residential area. Within 91 m of a bus maintenance facility. | | | | | | |
| SPECTROMETER | INLET CHARACTERISTICS (FLOW RATE [L/MIN] SIZE INLET DRYER AERODYNAMIC DIAMETER, μ M PARTICLE SIZING METHOD) | VOLATILIZATION/ IONIZATION METHOD ^a | | MASS SPECTROMETER ^c | OTHER | |
| RSMS-III | 0.2 – 18, based on particle size chosen None Nafion 0.045 – 1.3 Aerodynamic focusing; Need to pre-select sizes to be analyzed | LDI, ArF laser, 193 nm | | TOF with dual ion polarity | At each size set point, aerosol was sampled in each cycle for either 10 min or until mass spectra from 30 particles were collected, whichever came first. | |
| Lake et al. ^{140, 141} | | | | | | |
| Utilizing both positive and negative ion detection enables detection of more species. However, detection efficiencies of negative ions decreased for smaller particles. | | | | | | |
| SO ₄ ⁺ concentration (number or mass) was not accurately quantified. | | | | | | |
| RSMS-III was most efficient in 0.050 to 0.77 μ m range. | | | | | | |
| Particle compositions could be related to specific source categories. | | | | | | |

A.1.2. Networks

Table A-19. Relevant Spatial Scales for PM₁₀, PM_{2.5}, and PM_{10-2.5} Measurement

| Spatial Scales | PM ₁₀ | PM _{2.5} | PM _{10-2.5} |
|---------------------------------|---|---|--|
| Microscale (~ 5 – 100 m) | <p>This scale would typify areas such as downtown street canyons, traffic corridors, and fence line stationary source monitoring locations where the general public could be exposed to maximum PM₁₀ concentrations. Microscale particulate matter sites should be located near inhabited buildings or locations where the general public can be expected to be exposed to the concentration measured. Emissions from stationary sources such as primary and secondary smelters, power plants, and other large industrial processes may, under certain plume conditions, likewise result in high ground level concentrations at the microscale. In the latter case, the microscale would represent an area impacted by the plume with dimensions extending up to approximately 100 meters. Data collected at microscale sites provide information for evaluating and developing hot spot control measures.</p> | <p>This scale would typify areas such as downtown street canyons and traffic corridors where the general public would be exposed to maximum concentrations from mobile sources. In some circumstances, the microscale is appropriate for particulate sites; community-oriented SLAMS sites measured at the microscale level should, however, be limited to urban sites that are representative of long-term human exposure and of many such microenvironments in the area. In general, microscale particulate matter sites should be located near inhabited buildings or locations where the general public can be expected to be exposed to the concentration measured. Emissions from stationary sources such as primary and secondary smelters, power plants, and other large industrial processes may, under certain plume conditions, likewise result in high ground level concentrations at the microscale. In the latter case, the microscale would represent an area impacted by the plume with dimensions extending up to approximately 100 meters. Data collected at microscale sites provide information for evaluating and developing hot spot control measures. Unless these sites are indicative of population-oriented monitoring, they may be more appropriately classified as SPM.</p> | <p>This scale would typify relatively small areas immediately adjacent to: Industrial sources; locations experiencing ongoing construction, redevelopment, and soil disturbance; and heavily traveled roadways. Data collected at microscale stations would characterize exposure over areas of limited spatial extent and population exposure, and may provide information useful for evaluating and developing source-oriented control measures.</p> |
| Middle Scale (~ 100 – 500 m) | <p>Much of the short-term public exposure to coarse fraction particles (PM₁₀) is on this scale and on the neighborhood scale. People moving through downtown areas or living near major roadways or stationary sources, may encounter particulate pollution that would be adequately characterized by measurements of this spatial scale. Middle scale PM₁₀ measurements can be appropriate for the evaluation of possible short-term exposure public health effects. In many situations, monitoring sites that are representative of microscale or middle-scale impacts are not unique and are representative of many similar situations. This can occur along traffic corridors or other locations in a residential district. In this case, one location is representative of a neighborhood of small scale sites and is appropriate for evaluation of long-term or chronic effects. This scale also includes the characteristic concentrations for other areas with dimensions of a few hundred meters such as the parking lot and feeder streets associated with shopping centers, stadia, and office buildings. In the case of PM₁₀, unpaved or seldomly swept parking lots associated with these sources could be an important source in addition to the vehicular emissions themselves.</p> | <p>People moving through downtown areas, or living near major roadways, encounter particle concentrations that would be adequately characterized by this spatial scale. Thus, measurements of this type would be appropriate for the evaluation of possible short-term exposure public health effects of particulate matter pollution. In many situations, monitoring sites that are representative of microscale or middle-scale impacts are not unique and are representative of many similar situations. This can occur along traffic corridors or other locations in a residential district. In this case, one location is representative of a number of small scale sites and is appropriate for evaluation of long-term or chronic effects. This scale also includes the characteristic concentrations for other areas with dimensions of a few hundred meters such as the parking lot and feeder streets associated with shopping centers, stadia, and office buildings.</p> | <p>People living or working near major roadways or industrial districts encounter particle concentrations that would be adequately characterized by this spatial scale. Thus, measurements of this type would be appropriate for the evaluation of public health effects of coarse particle exposure. Monitors located in populated areas that are nearly adjacent to large industrial point sources of coarse particles provide suitable locations for assessing maximum population exposure levels and identifying areas of potentially poor air quality. Similarly, monitors located in populated areas that border dense networks of heavily-traveled traffic are appropriate for assessing the impacts of resuspended road dust. This scale also includes the characteristic concentrations for other areas with dimensions of a few hundred meters such as school grounds and parks that are nearly adjacent to major roadways and industrial point sources, locations exhibiting mixed residential and commercial development, and downtown areas featuring office buildings, shopping centers, and stadiums.</p> |

| Spatial Scales | PM ₁₀ | PM _{2.5} | PM _{10-2.5} |
|---|---|--|--|
| Neighborhood Scale (~ 500 m – 4 km) | Measurements in this category represent conditions throughout some reasonably homogeneous urban sub-region with dimensions of a few kilometers and of generally more regular shape than the middle scale. Homogeneity refers to the particulate matter concentrations, as well as the land use and land surface characteristics. In some cases, a location carefully chosen to provide neighborhood scale data would represent not only the immediate neighborhood but also neighborhoods of the same type in other parts of the city. Neighborhood scale PM ₁₀ sites provide information about trends and compliance with standards because they often represent conditions in areas where people commonly live and work for extended periods. Neighborhood scale data could provide valuable information for developing, testing, and revising models that describe the larger-scale concentration patterns, especially those models relying on spatially smoothed emission fields for inputs. The neighborhood scale measurements could also be used for neighborhood comparisons within or between cities. | Measurements in this category would represent conditions throughout some reasonably homogeneous urban sub-region with dimensions of a few kilometers and of generally more regular shape than the middle scale. Homogeneity refers to the particulate matter concentrations, as well as the land use and land surface characteristics. Much of the PM _{2.5} exposures are expected to be associated with this scale of measurement. In some cases, a location carefully chosen to provide neighborhood scale data would represent the immediate neighborhood as well as neighborhoods of the same type in other parts of the city. PM _{2.5} sites of this kind provide good information about trends and compliance with standards because they often represent conditions in areas where people commonly live and work for periods comparable to those specified in the NAAQS. In general, most PM _{2.5} monitoring in urban areas should have this scale. | Measurements in this category would represent conditions throughout some reasonably homogeneous urban sub-region with dimensions of a few kilometers and of generally more regular shape than the middle scale. Homogeneity refers to the particulate matter concentrations, as well as the land use and land surface characteristics. This category includes suburban neighborhoods dominated by residences that are somewhat distant from major roadways and industrial districts but still impacted by urban sources, and areas of diverse land use where residences are interspersed with commercial and industrial neighborhoods. In some cases, a location carefully chosen to provide neighborhood scale data would represent the immediate neighborhood as well as neighborhoods of the same type in other parts of the city. The comparison of data from middle scale and neighborhood scale sites would provide valuable information for determining the variation of PM _{10-2.5} levels across urban areas and assessing the spatial extent of elevated concentrations caused by major industrial point sources and heavily traveled roadways. Neighborhood scale sites would provide concentration data that are relevant to informing a large segment of the population of their exposure levels on a given day. |
| Urban Scale (~ 4 – 50 km) | This class of measurement would be used to characterize the particulate matter concentration over an entire metropolitan or rural area ranging in size from 4 to 50 kilometers. Such measurements would be useful for assessing trends in area-wide air quality, and hence, the effectiveness of large scale air pollution control strategies. Community-oriented PM _{2.5} sites may have this scale. | | |
| Regional Scale (~ 50 – 100s km) | These measurements would characterize conditions over areas with dimensions of as much as hundreds of kilometers. As noted earlier, using representative conditions for an area implies some degree of homogeneity in that area. For this reason, regional scale measurements would be most applicable to sparsely populated areas. Data characteristics of this scale would provide information about larger scale processes of particulate matter emissions, losses and transport. PM _{2.5} transport contributes to elevated particulate concentrations and may affect multiple urban and State entities with large populations such as in the eastern United States. Development of effective pollution control strategies requires an understanding at regional geographical scales of the emission sources and atmospheric processes that are responsible for elevated PM _{2.5} levels and may also be associated with elevated O ₃ and regional haze. | | |

^fNCORE is a network proposed to replace NAMS, as a component of SLAMS; NAMS are currently designated as national trends sites.

^hsurface meteorology includes wind direction and speed, temperature, precipitation, relative humidity, solar radiation (PAMS only).

ⁱPM₁₀ metals may include arsenic, beryllium, cadmium, chromium, lead, manganese, nickel, and others.

^jSome networks listed separately may also serve as subcomponents of other larger listed networks; as a result, some double counting of the number of individual monitors is likely.

^kThe number of sites indicated for tribal monitoring is actually the number of monitors, rather than sites. The number of sites with multiple monitors is probably < 80.

^lSunrise program estimates UV exposure levels through modeling - does not include measurements.

^mNEUBREW is a subset Original UV brewer network (UV Net); PRIMENET participated in UV Net program.

A.2. Ambient PM Concentration

A.2.1. Speciation Trends Network Site Data

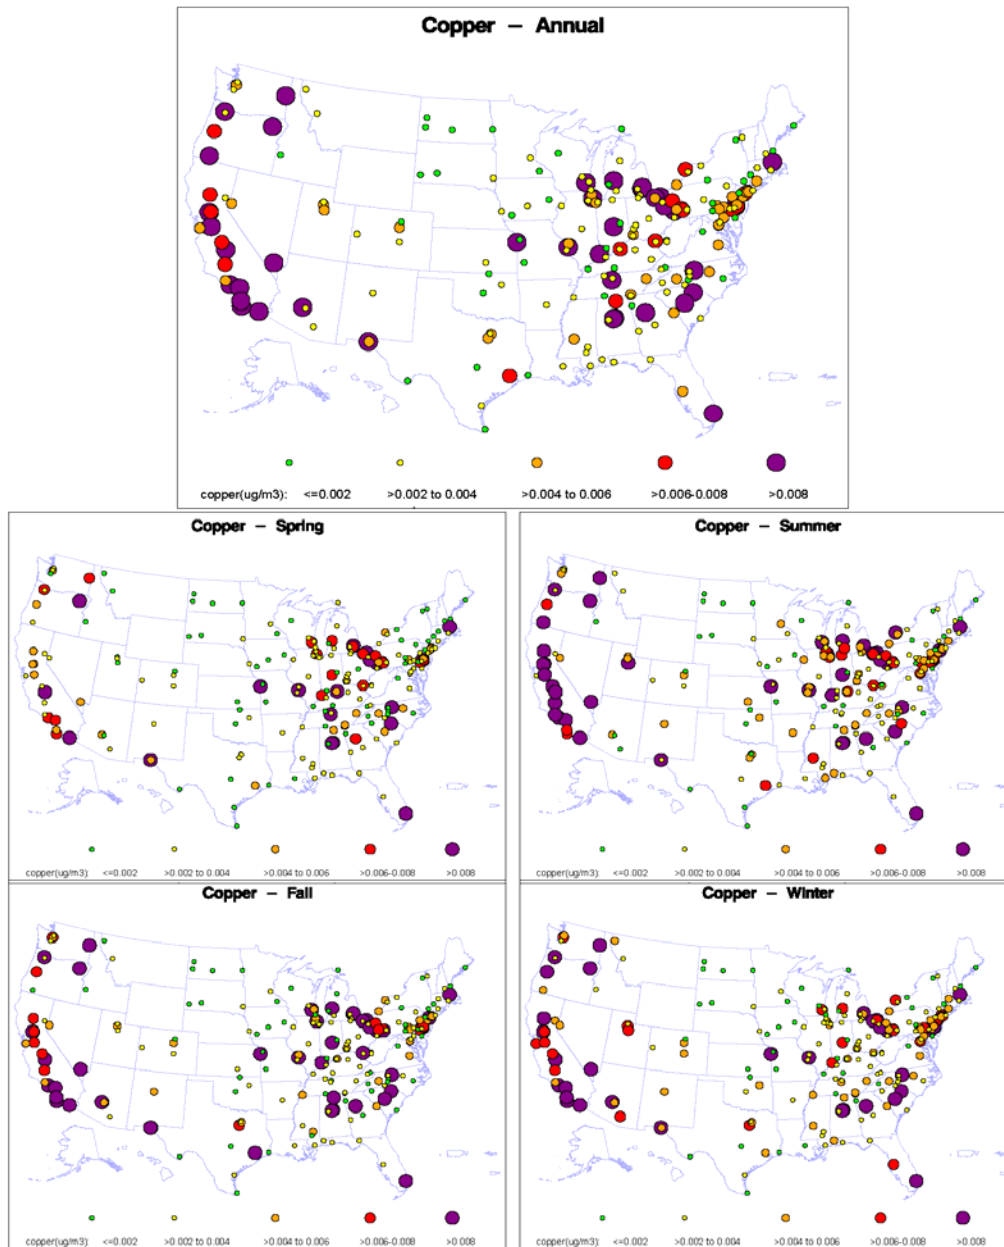

Figure A-29. Three-yr avg of 24-h PM_{2.5} Cu concentrations measured at CSN sites across the U.S., 2005-2007.

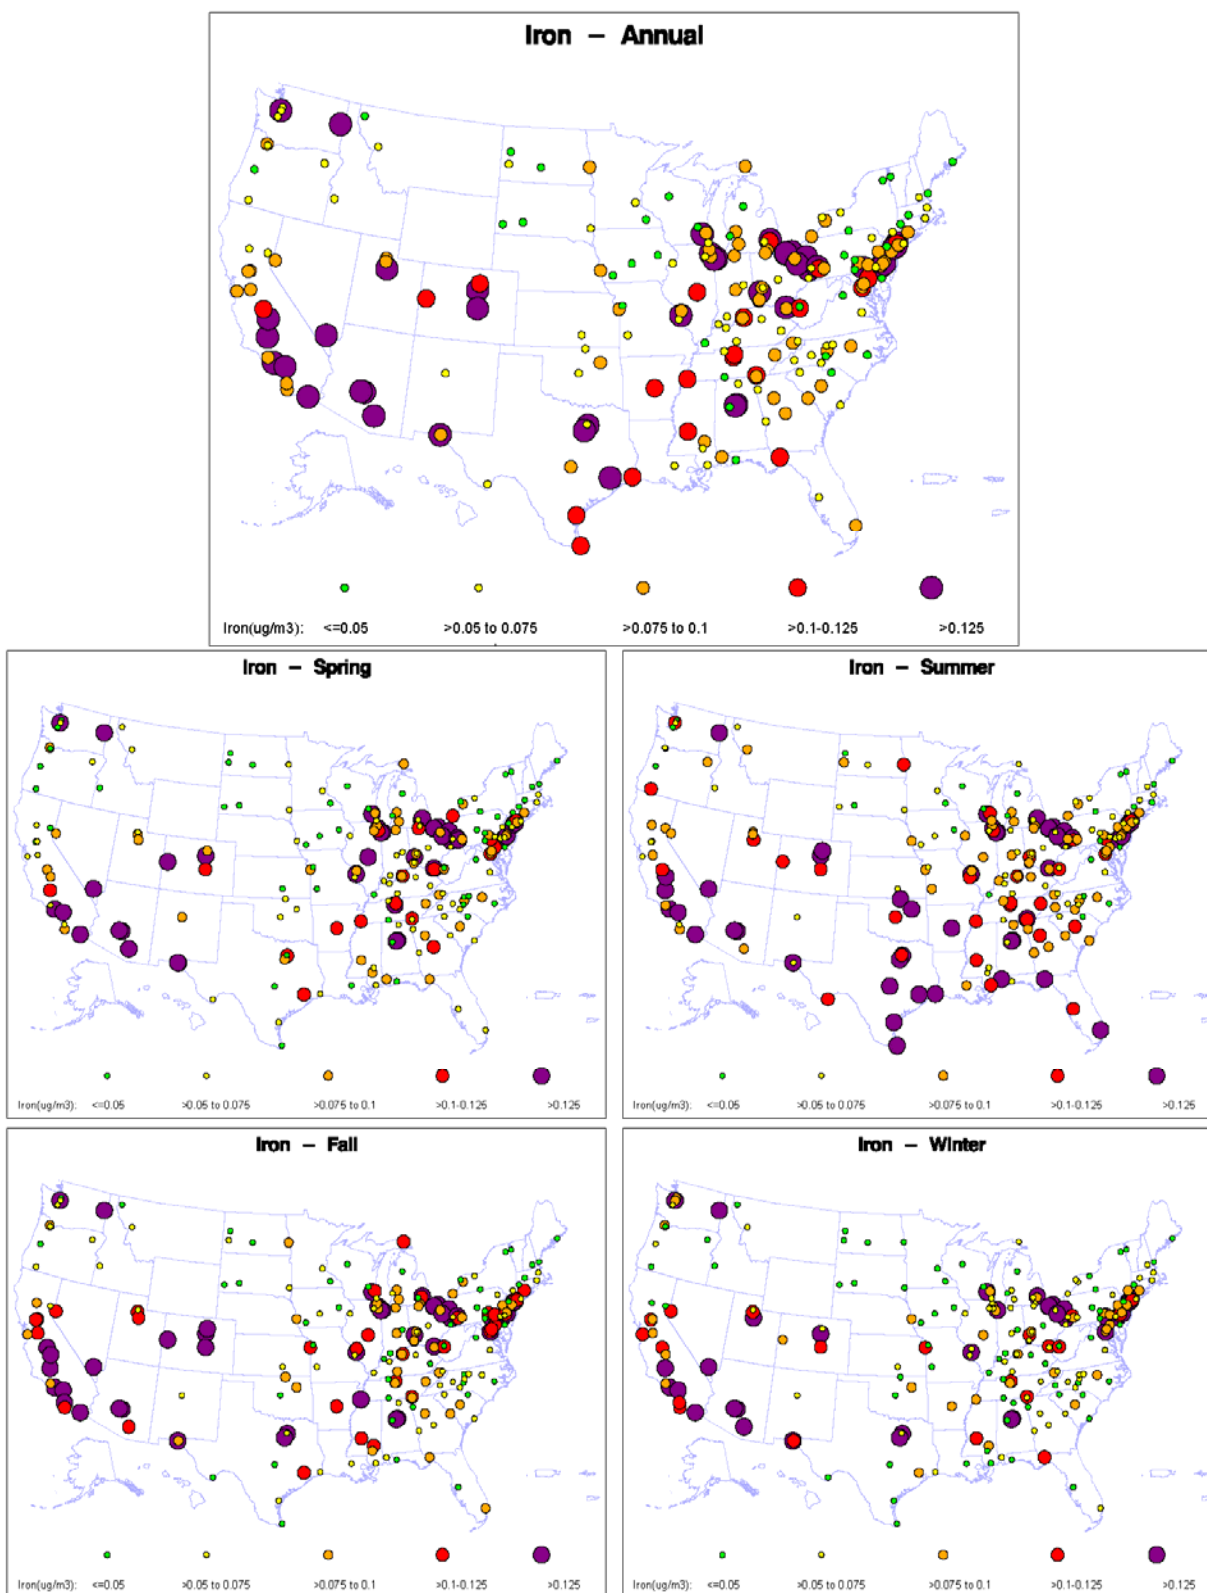

Figure A-30. Three-yr avg of 24-h PM_{2.5} iron concentrations measured at CSN sites across the U.S., 2005-2007

Figure A-31. Three-yr avg of 24-h PM_{2.5} nickel concentrations measured at CSN sites across the U.S., 2005-2007

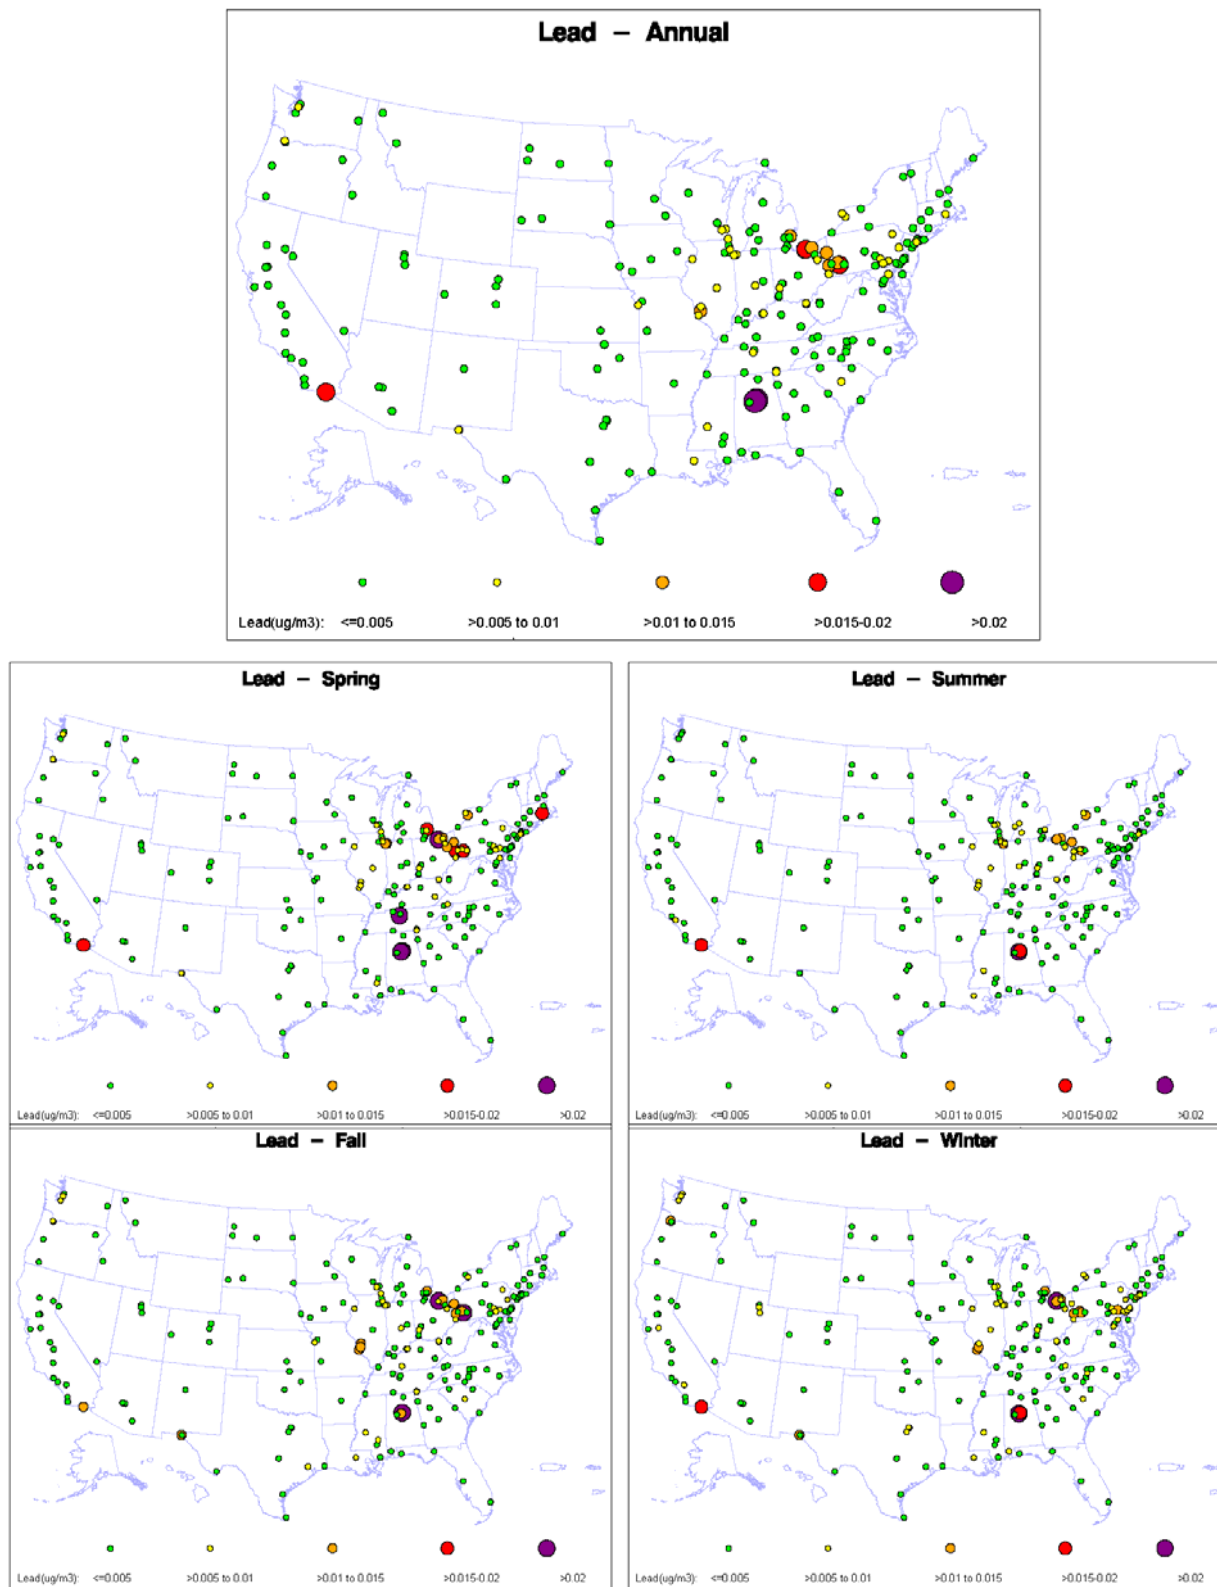

Figure A-32. Three-yr avg of 24-h PM_{2.5} lead concentrations measured at CSN sites across the U.S., 2005-2007

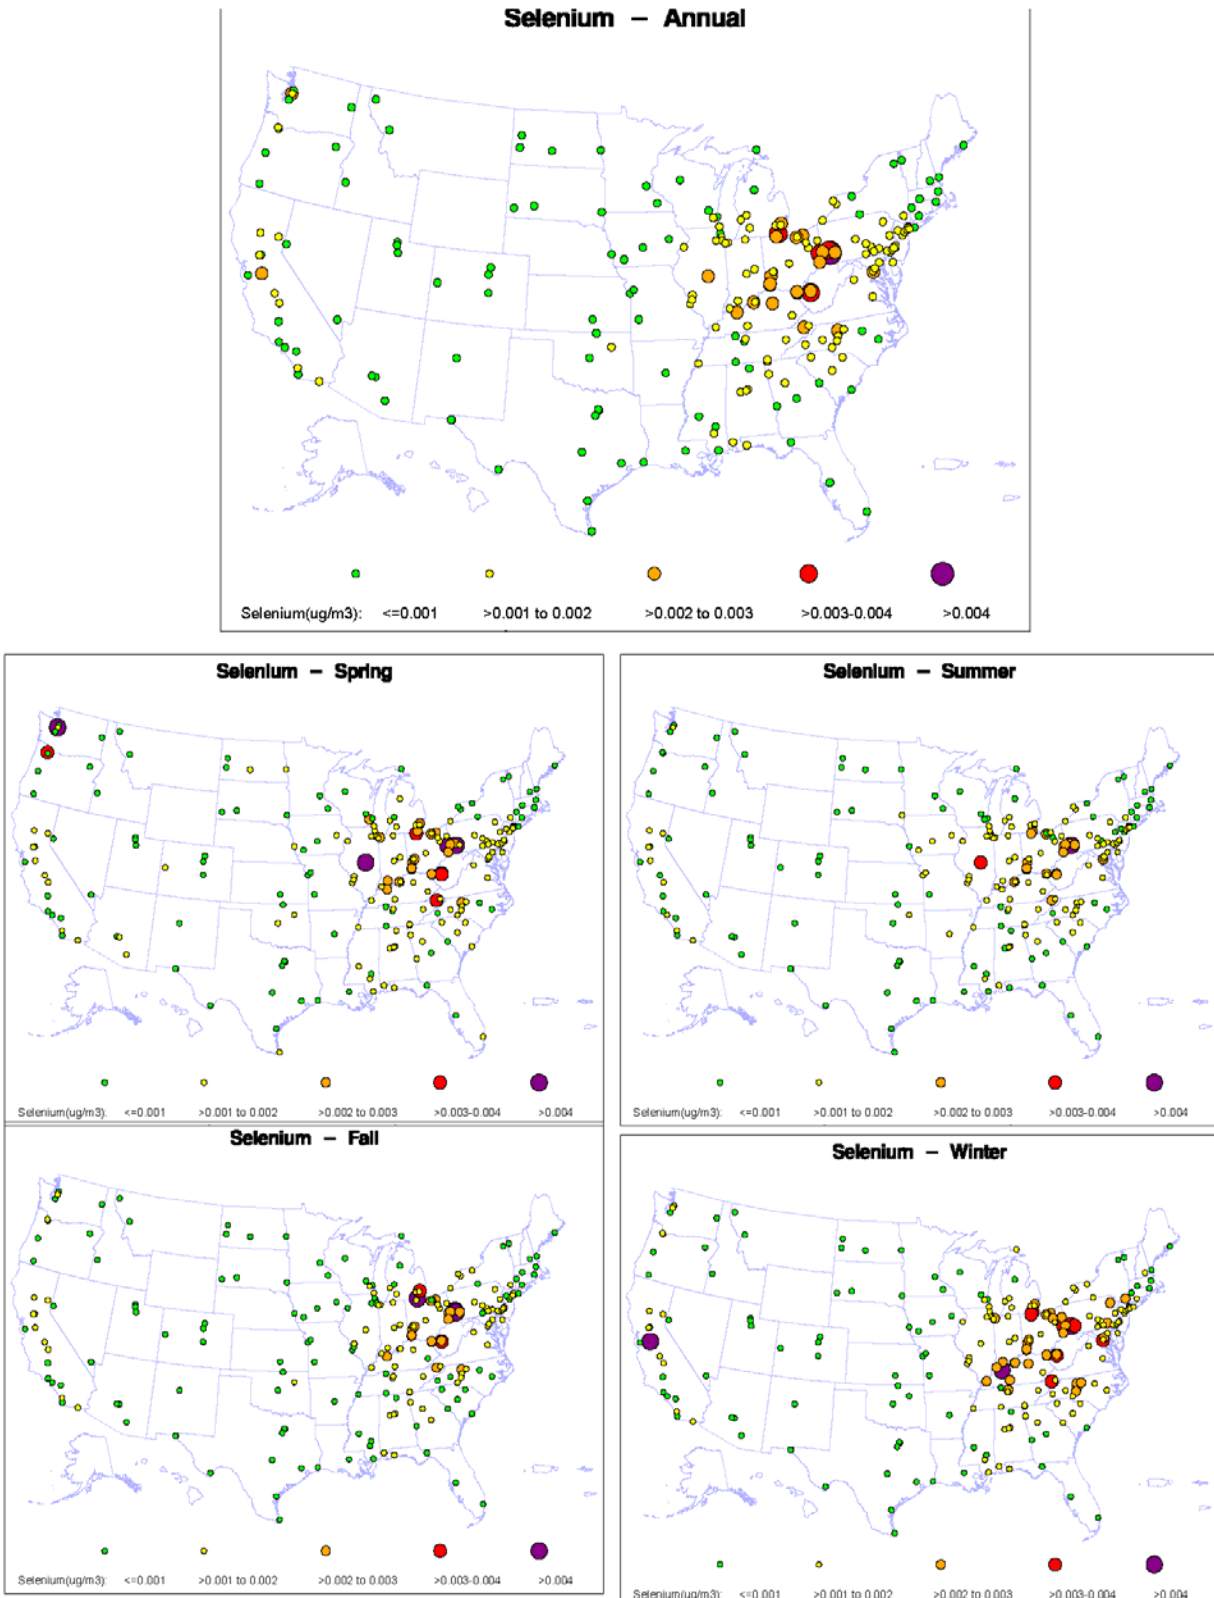

Figure A-33. Three-yr avg of 24-h PM_{2.5} selenium concentrations measured at CSN sites across the U.S., 2005-2007

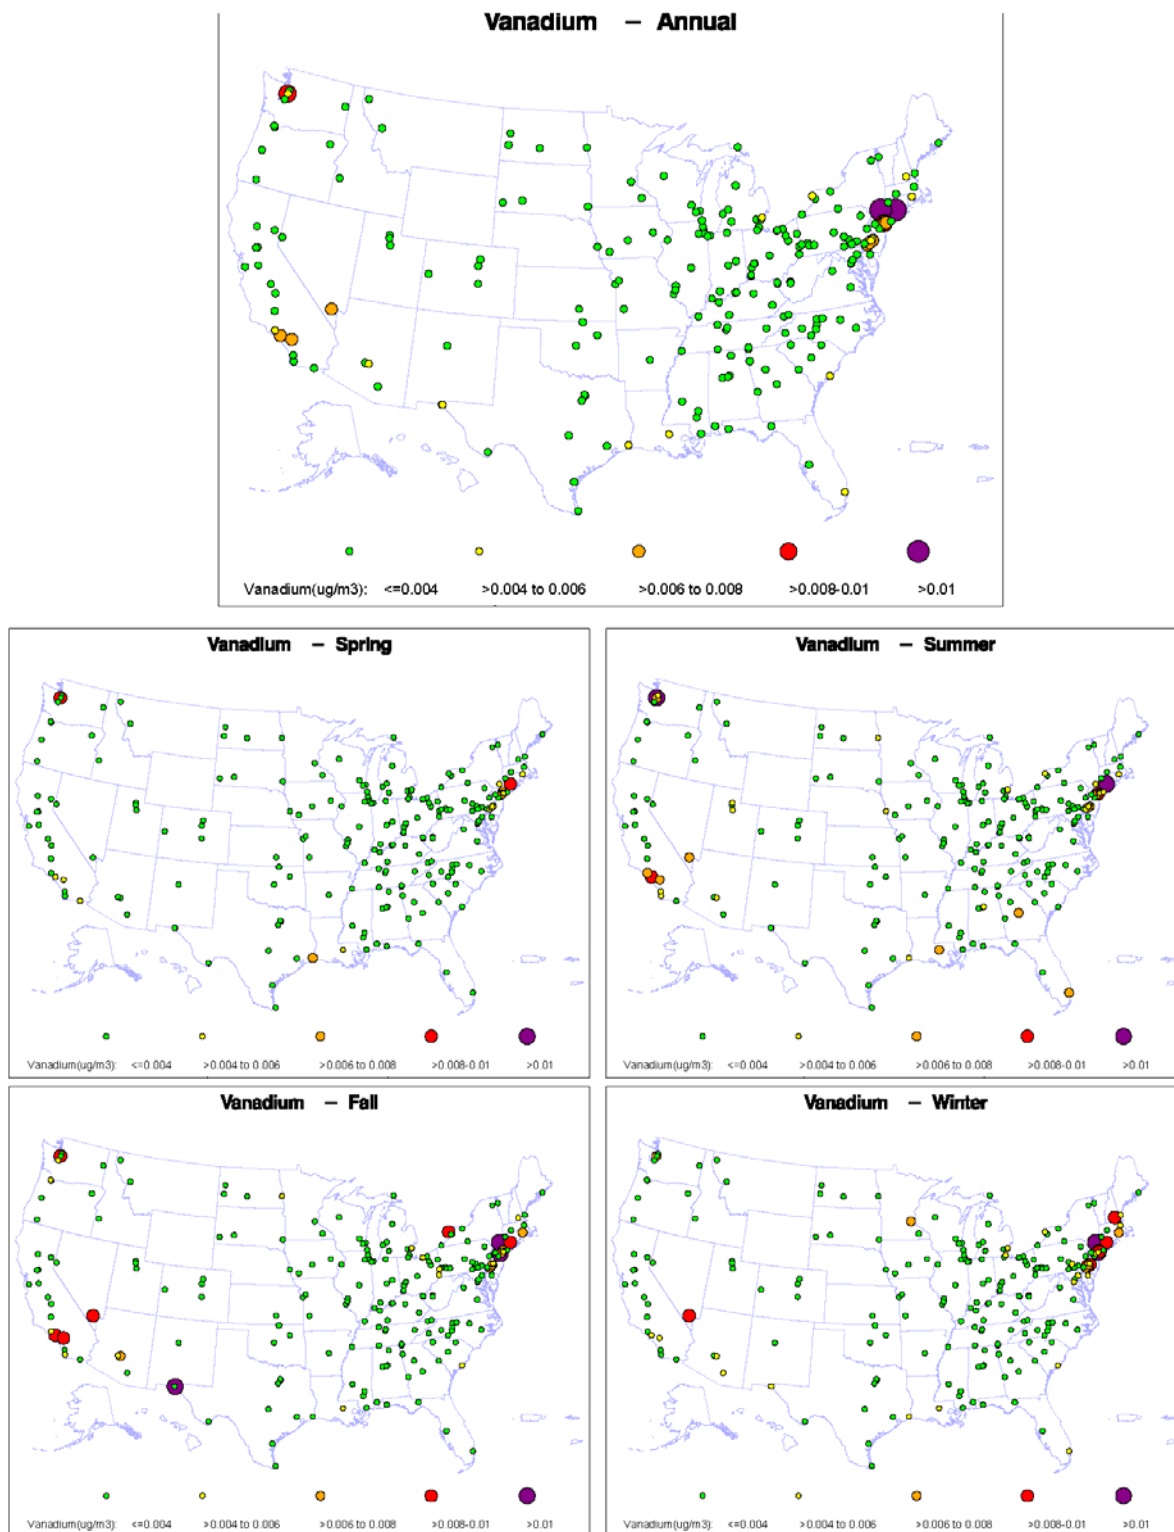

Figure A-34. Three-yr avg of 24-h PM_{2.5} vanadium concentrations measured at CSN sites across the U.S., 2005-2007

A.2.2. Intraurban Variability

The following figures and tables exemplify the intraurban variability among $PM_{2.5}$, $PM_{10-2.5}$ and PM_{10} measurements for select CSAs/CBSAs (2005-2007) including Atlanta, Birmingham, Chicago, Denver, Detroit, Houston, New York City, Philadelphia, Phoenix, Riverside, Seattle and St. Louis. Maps are included to show monitor locations relative to major roadways. Box plots show the median and interquartile range of concentrations with whiskers extending to the 5th and 95th percentiles at each site during (1) winter (December-February); (2) spring (March-May); (3) summer (June-August); and (4) fall (September-November). Tables of inter-sampler comparison statistics and scatter plots of inter-sampler correlation vs. distance illustrate variability present in each area.

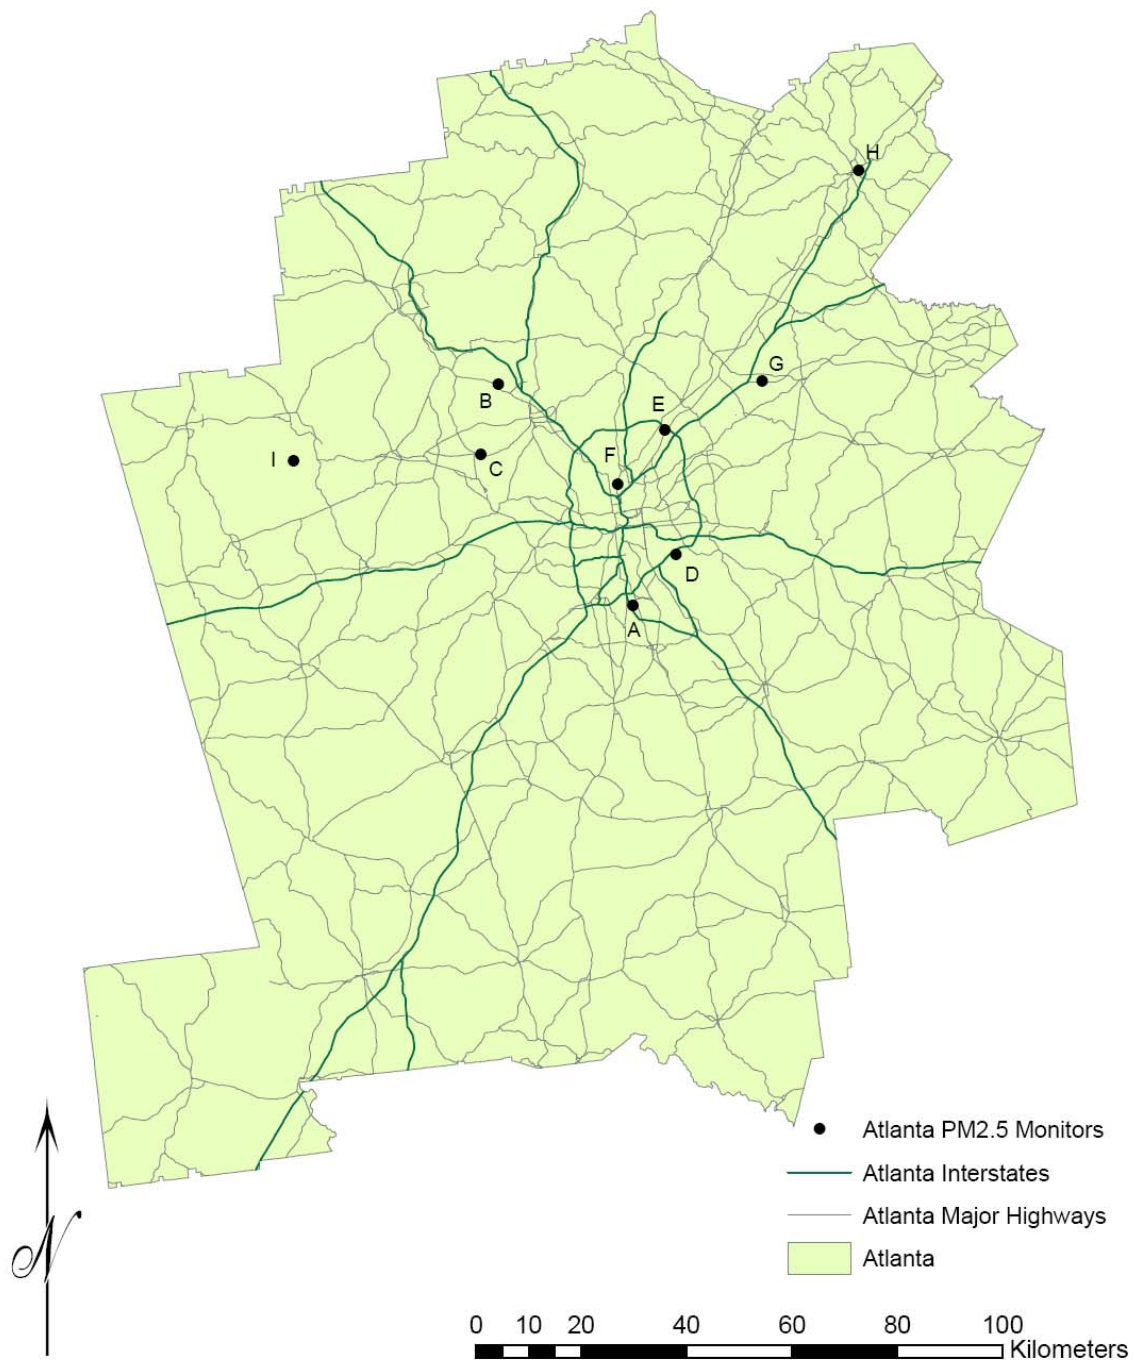

Figure A-35. PM_{2.5} monitor distribution and major highways, Atlanta, GA.

Figure A-36. Box plots illustrating the seasonal distribution of 24-h avg PM_{2.5} concentrations for Atlanta, GA.

Table A-1. Inter-sampler correlation statistics for each pair of PM_{2.5} monitors reporting to AQS for Atlanta, GA.

Figure A-52. PM_{2.5} inter-sampler correlations as a function of distance between monitors for Houston, TX.

Figure A-53. PM_{2.5} monitor distribution and major highways, New York City, NY.

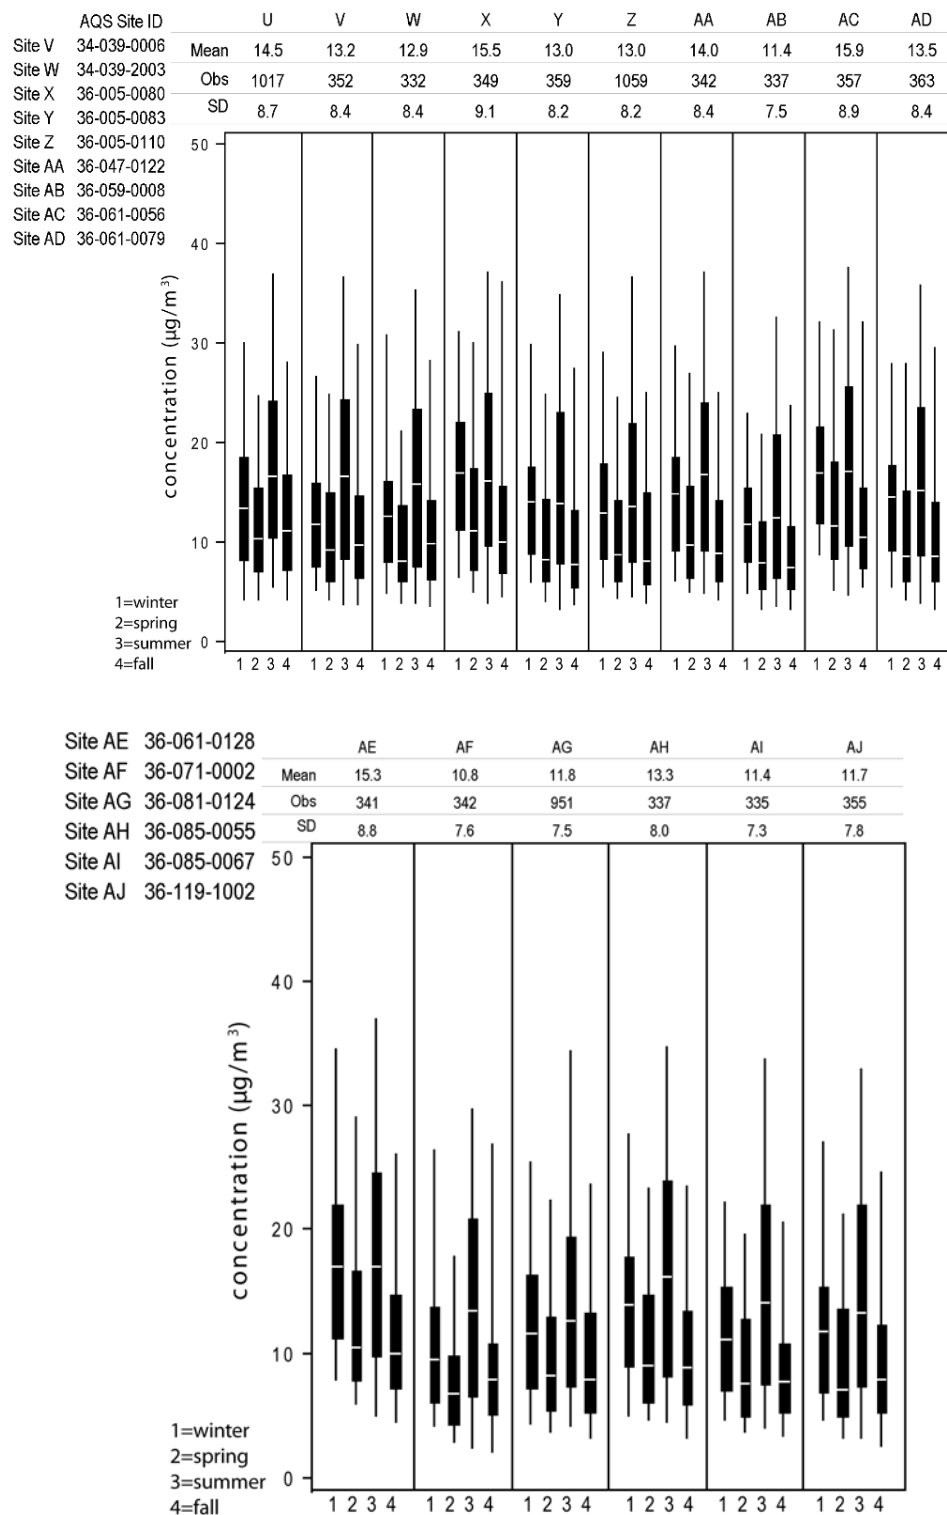

Figure A-54. Box plots illustrating the seasonal distribution of 24-h avg PM_{2.5} concentrations for New York City, NY.

Table A-7. Inter-sampler correlation statistics for each pair of PM_{2.5} monitors reporting to AQS for New York City, NY.

A.3. Source Apportionment

A.3.1. Type of Receptor Models

Table A-46. Different receptor models used in the Supersite source apportionment studies: chemical mass balance.

| Receptor Model | Description | Strengths and Weaknesses |
|--|--|---|
| <p>Effective Variance CMB 42,121</p> <p>(Note that all models based on eq 1 or 2 are CMB equations. The term CMB used here reflects the historical solution in which source profiles are explicitly used as model input and a single sample effective variance solution is reported.)</p> <p>CMB software is currently distributed by EPA. The most recent version is the CMB 8.2, which is run in the Microsoft Windows system.</p> | <p>Principle</p> <p>Ambient chemical concentrations are expressed as the sum of products of species abundances in source emissions and source contributions (eq 1 or 2). These equations are solved for the source contribution estimates when ambient concentrations and source profiles are input. The single-sample effective variance least squares¹²² is the most commonly used solution method because it incorporates uncertainties of ambient concentrations and source profiles in the estimate of source contributions and their uncertainties. This reduced to the tracer solution when it is assumed that there is one unique species for each source. Choices of source profiles should avoid collinearity, which occurs when chemical compositions of various source emissions are not sufficiently different.¹²¹</p> <p>Data Needs</p> <p>CMB requires source profiles, which are the mass fractions of particulate or gas species in source emissions. The species and particle size fraction measured in source emissions should match those in ambient samples to be apportioned. Several sampling and analysis methods provide time-integrated speciation of PM_{2.5} and volatile organic compounds (VOCs) for CMB. Source profiles are preferably obtained in the same geographical region as the ambient samples, although using source profiles from different regions is commonly practiced in the literature. The practitioner needs to decide the source profiles and species being included in the model, on the basis of the conceptual model and model performance measures.</p> <p>Output</p> <p>Effective variance CMB determines, if converged, source contributions to each sample in terms of PM or VOC mass. CMB also generates various model performance measures, including correlation R², deviation σ^2, residue/uncertainty ratio, and MPIN matrix that are useful for refining the model inputs to obtain the best and most meaningful source apportionment resolution.</p> | <p>Strengths</p> <p>Software available providing a good user interface.</p> <p>Provides quantitative uncertainties on source contribution estimates based on input concentrations, measurement uncertainties, and collinearity of source profiles.</p> <p>Quantifies contributions from source types with single particle and organic compound measurements.</p> <p>Weaknesses</p> <p>Completely compatible source and receptor measurements are not commonly available.</p> <p>Assumes all observed mass is due to the sources selected in advance, which involves some subjectivity.</p> <p>Chemically similar sources may result in collinearity without more specific chemical markers.</p> <p>Typically does not apportion secondary particle constituents to sources. Must be combined with profile aging model to estimate secondary PM.</p> |

Table A-47. Different receptor models used in the Supersites source apportionment studies: factor analysis.

| Receptor Model | Description | Strengths and Weaknesses |
|---|--|---|
| <p>PMF123,124</p> <p>PMF_x (PMF2 and PMF3) software is available from Dr. Pentti Paatero at the University of Helsinki, Finland. This software is a Microsoft DOS application. EPA distributes EPA PMF76 version 1.1 as a Microsoft Windows application with better user interface.</p> | <p>Principle</p> <p>PMF_x contains PMF2 and PMF3. PMF2 solves the CMB equations (i.e., eqs 2 and 3) using an iterative minimization algorithm. Source profiles F_{ij} and contribution S_{jt} are solved simultaneously. The non-negativity constraint is implemented in the algorithm to decrease the number of possible solutions (local minimums) in the PMF analyses, because both source profile and contribution should not contain negative values. There is rotational ambiguity in all two-way factor analyses (i.e., F_{ij} and S_{jt} matrices may be rotated and still fit the data). PMF2 allows using the FPEAK parameter to control the rotation. A positive FPEAK value forces the program to search such solutions where there are many zeros and large values but few intermediate values in the source matrix F_{ij}. F_{key} can further bind individual elements in F_{ij} to zero. On the basis of a similar algorithm, PMF3 solves a three-way problem.</p> <p>PMF_x and UNMIX estimate F_{ij} and S_{jt} by minimizing:</p> $Q \text{ or } \chi^2 = \sum_i \sum_t [E_{it}/\sigma_{it}]^2 = \sum_i \sum_t [(C_{it} - \sum_j F_{ij}S_{jt})/\sigma_{it}]^2$ <p>(A-1)</p> <p>Where the weighing factor, σ_{it}, represents the magnitude of E_{it}, PMF_x limits solutions of eq 2 to non-negative F_{ij} and S_{jt}.</p> <p>Data Needs</p> <p>A large number of ambient samples (usually much more than the number of factors in the model) are required to produce a meaningful solution. Species commonly used in PMF are also those in CMB. Weighting factors associated with each measurement need to be assigned before analysis. The practitioner also needs to decide the number of factors, FPEAK, and F_{key} in the model.</p> <p>Output</p> <p>PMF_x reports all the elements in F_{ij} and S_{jt} matrices (PMF2). It also calculates model performance measures such as deviation Q^2 and standard deviation of each matrix element. The practitioner needs to interpret the results linking them to source profiles and source contributions.</p> | <p>Strengths</p> <p>Software available.</p> <p>Can handle missing or below-detection-limit data.</p> <p>Weights species concentrations by their analytical precisions.</p> <p>Downweight outliers in the robust mode.</p> <p>Derives source profiles from ambient measurements as they would appear at the receptor (does not require source measurements).</p> <p>Weaknesses</p> <p>Requires large (> 100) ambient datasets.</p> <p>Need to determine the number of retaining factors.</p> <p>Requires knowledge of source profiles or existing profiles to verify the representativeness of calculated factor profiles and uncertainties of factor contributions.</p> <p>Relies on many parameters/initial conditions adjustable to model input; sensitive to the preset parameters.</p> |
| <p>ME2125</p> <p>ME2 code is available from Dr. Pentti Paatero at the University of Helsinki, Finland as a Microsoft DOS application.</p> | <p>Principle</p> <p>The PMF_x algorithm is derived from ME2. Unlike PMF_x that is limited to questions in the form of eq 1 or 2, ME2 solves all models in which the data values are fitted by sums of products of unknown (and known) factor elements. The first part of the algorithm interprets instructions from the user and generates a table that specifies the model. The second part solves the model using an iterative minimization approach. Additional constraints could be programmed into the model to reduce the ambiguity in source apportionment. These constraints may include known source profiles and/or contributions (e.g., contributions are known to be zero in some cases).</p> <p>Data Needs</p> <p>Data needs are similar to those of PMF_x but are more flexible. In theory, any measured or unknown variables may be included in the model as long as they satisfy linear relationships. The users need to specify the model structure, the input, and the output.</p> <p>Output</p> <p>ME2 calculates and reports all unknown variables in the model.</p> | <p>Strengths</p> <p>Software available.</p> <p>Can handle user-specified models.</p> <p>Possibility to include all measured variables into the model, such as speciated concentration over different time scales, size distributions, meteorological variables, and noise parameters.</p> <p>Weaknesses</p> <p>Require substantial training to access the full feature of the software and develop a model.</p> <p>Generally requires large ambient datasets.</p> <p>Need to assume linear relationships between all variables.</p> <p>Relies on many parameters/initial conditions adjustable to model input; sensitive to the preset parameters.</p> |

| Receptor Model | Description | Strengths and Weaknesses |
|--|--|--|
| <p>UNMIX ^{29,44,126}</p> <p>UNMIX code is available from Dr. Ron Henry at the University of Southern California as an MatLab application. A stand-alone version (UNMIX version 6) is also available from EPA.</p> | <p>Principle</p> <p>UNMIX views each sample as a data point in a multidimensional space with each dimension representing a measured species. UNMIX solves eqs 2 and 3 by using a principle component analysis (PCA) approach to reduce the number of dimensions in the space to the number of factors that produce the data, followed by an unique “edge detection” technique to identify “edges” defined by the data points in the space of reduced dimension (e.g., Figures 1 and 3). The number of factors is estimated by the NUMFACT algorithm in advance127, which reports the R² and signal-to-noise (S/N) ratio associated with the first N principle components (PCs) in the data matrix. The number of factors should coincide with the number of PCs with S/N ratio > 2. Once the data are plotted on the reduced space, an edge is actually a hyperplan that signifies missing or small contribution from one or more factors. Therefore, UNMIX searches all the edges and uses them to calculate the vertices of the simplex, which are then converted back to source composition and contributions. Geometrical concepts of self-modeling curve resolution are used to ensure that the results obey (to within error) non-negativity constraints on source compositions and contributions.</p> <p>Data Needs</p> <p>A large number of ambient samples (usually much more than the number of factors in the model) are required to achieve a meaningful solution. Species commonly used in UNMIX are also those in CMB. The measurement precision is not required. The practitioner needs to specify the number of factors on the basis of the NUMFACT results.</p> <p>Output</p> <p>UNMIX determines all the elements in the factor (F_{ij}) and contribution (S_{jt}) matrices. It also calculates the uncertainty associated with the factor elements and model performance measures including: (1) R², (2) S/N ratio, and (3) strength.</p> | <p>Strengths</p> <p>Software available with graphical user interface.</p> <p>Does not require source measurements.</p> <p>Provide graphical problem diagnostic tools (e.g., species scatter plot).</p> <p>Provide evaluation tools (e.g., R², S/N ratio).</p> <p>Weaknesses</p> <p>Requires large (> 100) ambient datasets.</p> <p>Need to assume or predetermine number of retained factors.</p> <p>Does not make explicit use of errors or uncertainties in ambient measurements.</p> <p>Cannot use samples containing missing data in any species.</p> <p>Limited to a maximum of 7 or 14 (UNMIX version 6) factors.</p> <p>Can report multiple or no solutions.</p> <p>Requires knowledge of existing source profiles to evaluate the solutions.</p> |

|--|--|--|
| <p>PDRM⁹⁷</p> <p>PDRM was developed under the Supersites Program and requires MatLab or equivalent software to perform the calculation.</p> | <p>Principle</p> <p>PDRM estimates contributions from selected stationary sources for a receptor site using high time-resolution measurements and meteorological data. In PDRM, eq 2 is modified to:</p> $C_k = \sum_j ER_{ij} \left(\frac{X}{Q} \right)_{jt} + E_k \quad (A-2)$ <p>where ER_{ij} is interpreted as the emission rate of species i from stationary source j and $(X/Q)_t$ is the meteorological dispersion factor averaged over the time interval t. Equation 4 is solved for ER_{ij} and $(X/Q)_t$ simultaneously by a nonlinear α minimizing the objective function, FUN:</p> $FUN = \sum_{i=1}^I \sum_{t=1}^n \sum_{j=1}^n \left[ER_{ij} \left(\frac{X}{Q} \right)_{jt}^{PDRM} - C_k \right]^2 \quad (A-3)$ <p>Because the number of solutions for a product of unknowns is infinite, additional constraints are set up for $(X/Q)_t$ on the basis of the Gaussian plume model, thus:</p> $LB \left(\frac{X}{Q} \right)_{jt}^{Met} \leq \left(\frac{X}{Q} \right)_{jt}^{PDRM} \leq UB \left(\frac{X}{Q} \right)_{jt}^{Met}$ $\left(\frac{X}{Q} \right)_{jt}^{Met} = \frac{1}{2\pi\sigma_y\sigma_z u} \exp\left(-\frac{1}{2}\frac{y^2}{\sigma_y^2}\right) \left\{ \exp\left[-\frac{1}{2}\left(\frac{z-h}{\sigma_z}\right)^2\right] + \exp\left[-\frac{1}{2}\left(\frac{z+h}{\sigma_z}\right)^2\right] \right\} \quad (A-4)$ <p>Eqs 6 and 7 limit the solution of eq 5 within the lower (LB) and upper (UB) bound of those predicted by the Gaussian plume model using different parameterizations.</p> <p>Data Needs</p> <p>PDRM requires speciated measurements at a higher time-resolution than typical CMB or PMF applications because of the fast-changing meteorological parameters. PDRM also requires data for eq 7: transport speed (u), lateral and vertical dispersion parameters (σ_y and σ_z), and stack height (h).</p> <p>Output</p> <p>PDRM determines emission rates and contributions from each point source considered in the model at the same time resolution as the measurement.</p> | <p>Strengths</p> <ul style="list-style-type: none"> Explicitly include meteorological information and stack configuration of stationary sources into the model. Do not require source measurements. Do not need to interpret the relations between factors and sources. Commercial software (e.g., MatLab) available for performing nonlinear α. Suitable for high time-resolution measurement. <p>Weaknesses</p> <ul style="list-style-type: none"> Can only handle stationary sources but not area or mobile sources. Need to assume that only stationary sources are considered in the model contribute significantly for a measurement at the receptor site. Do not account for uncertainty in the measurement. Meteorological data may not be always available or accurate. Gaussian plume model may not be representative of the actual atmospheric dispersion. Sensitive to the imposed constraints (UB and LB). |

|----------------|---|--|
| PLS128 | <p>Principle</p> <p>PLS examines the relationships between a set of predictor (independent) and response (dependent) variables. It assumes that the predictor and response variables are controlled by independent “latent variables” less in number than either the predictor or the response variables. In recent applications,⁸⁶ PM chemical composition and size distribution are used as predictor (X) and response (Y) variables, respectively. Eq 2 is modified to:</p> $X_k = \sum_i T_{if} P_{if} + E_k$ $Y_k = \sum_i U_{if} C_{if} + D_k$ <p>where T and U are matrices of so-called “latent variables,” and P and C are loading matrices. If X and Y are correlated to some degree, T and U would show some similarity. Equations 8 and 9 are solved by an iterative algorithm “NIPALS,” which attempts to minimize E, D, and the difference between T and U simultaneously. If T and U end up being close enough, the X and Y variables can be explained by the same latent variables. These latent variables may then be interpreted as source or source categories.</p> <p>Data Needs</p> <p>Typical applications of PLS require both chemical speciated and size-segregated measurements. The practitioner needs to decide the number of latent variables on the basis of the correlation of resulting T and U matrices.</p> <p>Output</p> <p>PLS calculates latent variables, which are common factors best explaining the predictor and response variables, and the residues from fitting. R_x and R_y.</p> $R_x = 1 - \text{var}(E)/\text{var}(X)$ $R_y = 1 - \text{var}(D)/\text{var}(Y)$ <p>indicate the degree to which variables X and Y are explained by the latent variables.</p> | <p>Strengths</p> <p>Fit two types of measurements (e.g., chemistry and size) with common factors. Provide more information to identify sources.</p> <p>Analyze strongly collinear and noisy dataset.</p> <p>Do not require source measurements.</p> <p>Weaknesses</p> <p>Requires large (> 100) ambient datasets.</p> <p>Difficult to relate latent variables to any physical quantities.</p> <p>Do not provide quantitative source contribution estimates.</p> <p>Need to decide the number of latent variables.</p> <p>Do not explicitly make use of measurement uncertainties.</p> <p>Can result in no solution.</p> |

|---|--|--|
| <p>EF^{129,130}</p> <p>The EF method may use a MLR algorithm, which is available in most statistical and spreadsheet software</p> | <p>Principle</p> <p>A tracer (or marker) for a particular source or source category is a species enriched heavily in the source emission against other species and other sources. Using EFs, concentration of the <i>i</i>th pollutant at a receptor site at time <i>t</i> (i.e., $C_{i,t}$) can be expressed as:</p> $C_{i,t} = \sum_j \frac{1}{EF_{i,j}} C_{p,j,t} + Z_{i,t} = \sum_j \left(\frac{F_i}{F_j} \right) C_{p,j,t} + Z_{i,t} \quad (A-7)$ <p>where the enrichment factor $EF_{i,j}$ is the ratio of emission rate of the pollutant of interest (F_i) and tracer species (F_j) from source <i>j</i>. $C_{p,j,t}$ is the concentration of tracer species for source <i>j</i> at time <i>t</i>, and $Z_{i,t}$ represents contributions from all other sources (including the background level). The solution for eq 12 is situation-dependent. $EF_{i,j}$ is usually unknown but may be estimated from source profiles, edges of a two-way scatter plot (e.g., Figures 1 and 3), or the ratio of $C_{i,t}$ to $C_{p,j,t}$ for a particular period when it is believed that a single source is dominant. In cases where $Z_{i,t}$ is a constant, $EF_{i,j}$ may be derived from MLR.</p> <p>Data Needs</p> <p>The minimum data needs include concentrations of all primary tracers at the receptor site. Known EFs or background levels are helpful.</p> <p>Output</p> <p>The EF method determines contributions to species <i>i</i> from each source considered in the model.</p> | <p>Strengths</p> <p>No special software needed.</p> <p>Indicate presence or absence of particular emitters.</p> <p>Provides evidence of secondary PM formation and changes in source impacts by changes in ambient composition.</p> <p>Could use a large (> 100) dataset or a small (e.g., < 10) dataset.</p> <p>Weaknesses</p> <p>Semiquantitative method, not specific especially when the EFs are unknown in advance.</p> <p>Limited to sources with unique markers.</p> <p>Tracer species must be exclusively from the sources or source categories examined.</p> <p>Provide very limited error estimates.</p> <p>More useful for source/process identification than for quantification.</p> |
| <p>NNLS^{131,132}</p> <p>The MatLab Optimization Toolbox provides a function "lsqnonneg" for performing the NNLS calculation.</p> | <p>Principle</p> <p>NNLS also solves the EF equation (eq 12 or equivalent) with known target species and tracer concentrations. Conventional MLR solutions to eq 12 may lead to negative EFs due to the uncertainty in measurements or colinearity in source contributions. This is avoided in the NNLS approach since additional non-negative constraints are built into the algorithm, i.e.:</p> $EF_{i,j} \geq 0 \quad (A-8)$ <p>Utilizing orthogonal decomposition, a NNLS problem can be reduced to the more familiar least-distance programming and solved by a set of iterative subroutines developed and tested by Lawson and Hanson.¹³¹ In a more general sense, NNLS linearly relates a response variable to a set of independent variables with only non-negative coefficients.</p> <p>Data Needs</p> <p>When applied to EF or MLR problems, NNLS requires the concentration of target (response) and tracer (independent) species.</p> <p>Output</p> <p>NNLS generates non-negative regression coefficients for an EF/MLR problem and these coefficients can be related to the source contributions.</p> | <p>Strengths</p> <p>Implemented by many statistical software packages.</p> <p>Generate only non-negative EFs or regression coefficients.</p> <p>Do not require source measurements.</p> <p>Possible to include meteorological or other (besides chemistry) data into the model.</p> <p>Weaknesses</p> <p>Require a large (> 100) set of ambient measurements.</p> <p>Semiquantitative method, not specific.</p> <p>Do not explicitly consider measurement uncertainties.</p> <p>Tracer species must be exclusively from the sources or source categories examined.</p> <p>Non-negative constraints may not be appropriate in some cases.</p> |

| Receptor Model | Description | Strengths and Weaknesses |
|--------------------|---|---|
| FAC ¹¹¹ | <p>Principle</p> <p>FAC provides a simple mean of estimating the SOA production rate using the emission inventories of primary precursor VOCs. FAC is actually a source-oriented modeling technique but it does not take into account all the atmospheric processes. FAC is defined as the fraction of SOA that would result from the reactions of a particular VOC:</p> $[SOA] = \sum_i FAC_i \times ([VOC_i]_0 \times \text{Fraction of VOC } i \text{ reacted})$ <p>where $[VOC_i]_0$ is the emission rate of VOC_i and $[SOA]$ is the formation rate of SOA. Equation 14 can be viewed as an extension of eq 12 but concentrations are replaced with emission rates and EFs are replaced with FACs. FAC and the fraction of VOC reacted under typical ambient conditions have been developed for a large number of hydrocarbons $> C_6$.¹¹¹ The most significant SOA precursors are aromatic compounds (especially toluene, xylene, and trimethylbenzenes) and terpenes. In most applications, these FACs are used directly to estimate SOA.</p> <p>Data Needs</p> <p>FAC requires the VOC emission inventory in the region of interest. The knowledge of O_3 and radiation intensity is also helpful for slight modifications of the FACs.</p> <p>Output</p> <p>FAC method estimates the total production rate of SOA.</p> | <p>Strengths</p> <p>Link SOA to primary VOC emissions so that SOA can also be treated as primary particles in the PM modeling.</p> <p>Simple and inexpensive.</p> <p>Weaknesses</p> <p>Ignore the influence of aerosol concentration and temperature-dependent gas-particle partitioning on SOA yield.</p> <p>Limited by the accuracy of VOC emission inventory.</p> <p>Do not directly infer the contribution of each source to ambient SOA concentration.</p> <p>Difficult to verify.</p> |

| Receptor Model | Description | Strengths and Weaknesses |
|------------------------|---|--|
| CPF ^{134,135} | <p>Principle</p> <p>CPF estimates the probability that a given source contribution from a given wind direction will exceed a predetermined threshold criterion (e.g., upper 25th percentile of the fractional contribution from the source of interest). The calculation of CPF uses source contributions (i.e., S_i in eq 2) determined for the receptor site and local wind direction data matching each of the source contributions in time. These data are then segregated to several sectors according to wind direction and the desired resolution (usually 36 sectors at a 10° resolution). Data with very low wind speed (e.g., < 0.1 m/sec) are usually excluded from analysis because of the uncertain wind direction. CPF is then determined by:</p> $CPF(\theta) = \frac{m_{\Delta\theta}}{n_{\Delta\theta}}$ <p style="text-align: right;">(A-10)</p> <p>where $m_{\Delta\theta}$ is the number of occurrences in the direction sector $\theta \pm \Delta\theta$ that exceeds the specified threshold, and $n_{\Delta\theta}$ is the total number of wind occurrences in that sector. Because wind direction is changing rapidly, high-time resolution measurements (e.g., minutes to hours) are preferred for a CPF analysis. If the calculated source contributions represent long-term averages, wind direction needs to be averaged over the same duration. In addition to source contribution, CPF can be applied directly to pollutant concentration measurements at a receptor site.</p> <p>Data Needs</p> <p>CPF requires the time series of source contributions at a receptor site, which is usually determined by CMB or factor analysis methods using speciated measurements at the site. CPF also requires wind direction and wind speed data averaged over the same time resolution as the sampling duration.</p> <p>Output</p> <p>CPF reports the probability of “high” contribution from a particular source or factor occurring within each wind direction sector. The results are often presented in a wind rose plot (e.g., Figure 6a).</p> | <p>Strengths</p> <p>Infer the direction of sources or factors relative to the receptor site.</p> <p>Provide verification for the source identification made by factor analysis method.</p> <p>Easy to implement.</p> <p>Weaknesses</p> <p>Criterion for the threshold is subjective.</p> <p>Absolute source contribution (or fractional contribution) may be influenced by other factors besides wind direction (e.g., wind speed, mixing height).</p> <p>Local and near-surface wind direction only has a limited implication for long-range transport.</p> <p>Easy to be biased by a small number of wind occurrences in a particular sector.</p> <p>Work better for stationary sources than area or mobile sources.</p> |

| Receptor Model | Description | Strengths and Weaknesses |
|------------------------|--|--|
| NPR ^{136,137} | <p>Principle</p> <p>NPR calculates the expected (averaged) source contribution as a function of wind direction following:</p> $S(\theta) = \frac{\sum_i K\left(\frac{\theta - W_i}{\Delta\theta}\right) \times S_i}{\sum_i K\left(\frac{\theta - W_i}{\Delta\theta}\right)} \quad (\text{A-11})$ <p>where W_i is the wind direction for the ith sample and S_i is the contribution from a specific source to that sample, determined from measurements at the receptor site. K is a weighting function called the kernel estimator. There are many possible choices for K. Henry et al. ¹³⁶ recommend either Gaussian or Epanechnikov functions. The most important decision in NPR is the choice of the smoothing parameter $\Delta\theta$. If $\Delta\theta$ is too large, $S(\Delta\theta)$ will be too smooth and meaningful peaks could be lost. If it is too small, $S(\Delta\theta)$ will have too many small, meaningless peaks. $\Delta\theta$ needs to be chosen according to the project-specific spatial distribution of sources. NPR also estimates the confidence intervals of $S(\Delta\theta)$ based on the asymptotic normal distribution of the kernel estimates, thus:</p> $\Delta S(\theta) = \frac{\sum_i K\left(\frac{\theta - W_i}{\Delta\theta}\right) \times (S_i - S(\theta))^2}{\left(\sum_i K\left(\frac{\theta - W_i}{\Delta\theta}\right)\right)^2} \quad (\text{A-12})$ <p>Data Needs</p> <p>NPR requires the same data as the CPF method, including the time series of source/factor contributions (or fractional contributions) at the receptor site and local wind direction data matching the sampling duration in time.</p> <p>Output</p> <p>NPR reports the distribution of source contribution as a function of wind direction and the confidence level associated with it.</p> | <p>Strengths</p> <p>Infer the direction of sources or factors relative to the receptor site.</p> <p>Provide verification for the source identification made by factor analysis method.</p> <p>Require no assumption about the function form of the relationship between wind direction and source contribution.</p> <p>Provide uncertainty estimates.</p> <p>Easy to implement.</p> <p>Weaknesses</p> <p>Choices for the kernel estimator and smoothing factor are subjective.</p> <p>Absolute source contribution (or fractional contribution) may be influenced by other factors besides wind direction (e.g., wind speed, mixing height).</p> <p>Local and near-surface wind direction only has a limited implication for long-range transport.</p> <p>Easy to be biased by a small number of wind occurrences in a particular sector.</p> <p>Work better for stationary sources than area or mobile sources.</p> |

|--|---|--|
| <p>TSA¹³⁸</p> <p>TSA requires the calculation of air parcel back trajectory, which is often accomplished using the HY-SPLIT model.115,139 HY-SPLIT version 4.5 is available at http://www.arl.noaa.gov/ready/hysplit4.html.</p> | <p>Principle</p> <p>Similar to CPF, TSA clusters the measured pollutant concentration or calculated source contribution according to the wind pattern. However, air parcel back trajectory, rather than local wind direction, is used. A back trajectory traces the air parcel backward in time from a receptor. The initial height is often between 200 and 1000 m above ground level where the wind direction could differ from the surface wind direction substantively. For each sample i, TSA obtains one or more trajectories and calculates their total residence time in the jth directional sector (τ_{ij}, i.e., the total number of 1-h trajectory end points that fall into the sector). The pollutant concentration or source contribution in the sample, S_i is then linearly apportioned into each directional sector according to τ_{ij} and averaged over all samples to produce the directional dependent pollutant concentration/source contribution for the period of interest:</p> $\bar{S}_j = \sum_i S_i \left(\frac{\tau_{ij}}{\sum_i \tau_{ij}} \right) / N \quad (A-13)$ <p>where N is the number of samples. Compared with CPF and NPR, TSA considers the entire air mass history rather than just the wind direction at the receptor.</p> <p>Data Needs</p> <p>TSA requires the time series of pollutant concentration or source contribution at the receptor site, and back trajectories initiated over the site during the sampling duration. Trajectory is usually calculated once every hour so TSA is more suitable for analyzing measurements of > 1-h resolution.</p> <p>Output</p> <p>TSA reports the avg pollutant concentration or source contribution as a function of wind direction based on back trajectory calculations.</p> | <p>Strengths</p> <p>Infer the direction of sources or factors relative to the sampling site.</p> <p>Provide verification for the source identification made by factor analysis method.</p> <p>Account for air mass transport over hundreds to thousands of kilometers and on the order of several days.</p> <p>Can represent plume spread from vertical wind shear at different hours of day by adjusting the initial height of back trajectories.</p> <p>Weaknesses</p> <p>Need to generate and analyze the back trajectory data.</p> <p>Uncertainty in back trajectory calculation increases with its length in time.</p> <p>Source contribution depends on not only trajectory residence time but also entrainment efficiency, dispersion, and deposition.</p> <p>Difficult to resolve the direction of more localized sources.</p> |

| Receptor Model | Description | Strengths and Weaknesses |
|--|---|--|
| <p>PSCF ¹⁴⁰</p> <p>PSCF requires the calculation of air parcel back trajectory, which is often accomplished using the HY-SPLIT model.^{115,139} HY-SPLIT version 4.5 is available at http://www.arl.noaa.gov/ready/hysplit4.html.</p> | <p>Principle</p> <p>Ensemble air parcel trajectory analysis refers to the statistical analysis on a group of trajectories to retrieve useful patterns regarding the spatial distribution of sources. Uncertainties associated with individual trajectory calculations largely cancel out for a sufficient number of trajectories or trajectory segments. As a popular ensemble back trajectory analysis, PSCF estimates the probability that an upwind area contributes to high pollutant concentration or source contribution. Back trajectories are first calculated for each sample at the receptor site. To determine the PSCF, a study domain containing the receptor site is divided into an array of grid cells. Trajectory residence time (the time it spends) in each grid cell is calculated for all back trajectories and for a subset of trajectories corresponding to "high" pollutant concentration or source contribution at the site. PSCF in cell (i,j) is then defined as:</p> $PSCF_{ij} = \frac{\text{Sum of "high" residence time in cell (i, j)}}{\text{Sum of all residence time in cell (i, j)}}$ <p style="text-align: right;">(A-14)</p> <p>The criterion for high pollutant concentration or source contribution is critical for the PSCF calculation. The 75th or 90th percentile of the concentration or factor is often used.^{113,141,142} Residence time can be represented by the number of trajectory end points in a cell.</p> <p>Data Needs</p> <p>Similar to TSA, PSCF calculation requires the time series of pollutant concentration or source contribution at the receptor site, and back trajectories initiated over the site during the sampling period. Trajectories should be calculated with 1-to 3-h segment to reduce the uncertainty from interpolation (if needed).</p> <p>Output</p> <p>PSCF reports the probability that an upwind area contributes to high pollutant concentrations or source contribution at the downwind receptor site. The results are often presented as a contour plot on the map. A high probability usually suggests potential source region (e.g., Figure 4b).</p> | <p>Strengths</p> <p>Infer the location of sources or factors relative to the sampling site.</p> <p>Provide verification for the source identification made by factor analysis method</p> <p>Account for air mass transport over hundreds to thousands of kilometers and on the order of several days.</p> <p>Resolve the spatial distribution of source strength (qualitatively).</p> <p>Weaknesses</p> <p>Need to generate and analyze the back trajectory data.</p> <p>Need to correct for the central tendency (residence time always increases toward the receptor site regardless of source contribution).</p> <p>Uncertainty in back trajectory calculation increases with its length in time.</p> <p>Source contribution depends on not only trajectory residence time but also entrainment efficiency, dispersion, and deposition.</p> <p>Difficult to resolve the location of more localized sources.</p> |

| Receptor Model | Description | Strengths and Weaknesses |
|--|--|---|
| <p>SQTBA^{117, 143}</p> <p>SQTBA requires the calculation of air parcel back trajectory, which is often accomplished using the HY-SPLIT model.^{115,139} HY-SPLIT version 4.5 is available at http://www.arl.noaa.gov/ready/hysplit4.html.</p> | <p>Principle</p> <p>SQTBA is another type of ensemble air parcel trajectory analysis. The concept of SQTBA is to estimate the “transport field” for each trajectory ignoring the effects of chemical reactions and deposition. Back trajectories are first calculated for each sample at the receptor site, and a study domain containing the receptor site is divided into an array of grid cells. SQTBA assumes that the transition probability that an air parcel at (x',y',t'), where x' and y' are spatial coordinates and t' means time, will reach a receptor site at (x,y,t) is approximately normally distributed along the trajectory with a standard deviation that increases linearly with time upwind^{144,145}, thus:</p> $Q(x, y, t x', y', z') = \frac{1}{2\pi(at')^2} \exp \left[-\frac{1}{2} \left(\left(\frac{X - x'(t')}{at'} \right)^2 + \left(\frac{Y - y'(t')}{at'} \right)^2 \right) \right] \quad (\text{A-15})$ <p>where (X,Y) is the coordinate of the grid center, a is the dispersion speed, and x'(t') and y'(t') represent the trajectory. The probability field, Q, for a given trajectory is then integrated over the upwind period, Δ, to produce a two-dimensional “natural” (nonweighted) transport field:</p> $T_k(x, y x', y') = \frac{\int_{-\tau}^0 Q(x, y, t x', y', z') dt'}{\int_{-\tau}^0 dt'}$ <p>After the transport field for each trajectory is established, they are weighted by the corresponding pollutant concentration or source contribution at the receptor site and summed to yield the overall SQTBA field.¹¹⁷</p> <p>Data Needs</p> <p>SQTBA requires the time series of pollutant concentration or source contribution at the receptor site, and back trajectories initiated over the site during the sampling period. Trajectories should be calculated with 1 to 3-h segment to reduce the uncertainty from interpolation (if needed).</p> <p>Output</p> <p>SQTBA put more weight on trajectories associated higher pollutant concentration or source contribution and therefore the resulting field may imply the major transport path.</p> | <p>Strengths</p> <p>Imply the location of sources or factors relative to the sampling site.</p> <p>Account for air mass transport over hundreds to thousands of kilometers and on the order of several days.</p> <p>Resolve the spatial distribution of source strength (qualitatively).</p> <p>Weaknesses</p> <p>Need to generate and analyze the back trajectory data.</p> <p>Need to correct for the central tendency (residence time always increases toward the receptor site regardless of source contribution).</p> <p>Need to estimate dispersion velocity.</p> <p>Involve complicated calculations.</p> <p>Physical meaning of the SQTBA field is unclear.</p> <p>Difficult to resolve the location of more localized sources.</p> |

| Receptor Model | Description | Strengths and Weaknesses |
|---|--|--|
| <p>RTWC ¹⁴⁶</p> <p>RTWC requires the calculation of air parcel back trajectory, which is often accomplished using the HY-SPLIT model.^{115,139} HY-SPLIT version 4.5 is available at http://www.arl.noaa.gov/ready/hysplit4.html</p> | <p>Principle</p> <p>As an ensemble air parcel trajectory analysis, RTWC requires back trajectories calculated for each sample at the receptor site, and a study domain containing the receptor site divided into an array of grid cells. RTWC assumes that no major pollutant sources are located along “clean” (associated with low pollutant concentrations) trajectories and that “polluted” trajectories picked up emissions along their paths. In practice, RTWC distributes pollutant concentrations at the receptor to upwind grid cells along the back trajectories according to the trajectory residence times in those cells.^{117,148}</p> $S_{ik} = S_k \frac{\text{resident time in cell } i}{\text{average residence time in each cell}}$ <p>(A-17)</p> <p>where S_k is the pollutant concentration or source contribution determined upon the arrival of trajectory k and S_{ik} is the redistributed pollutant concentration or source contribution for cell i upwind.</p> <p>RTWC is known for the problem of “tailing effect,” i.e., spurious source areas can be identified when cells are crossed by a very small number of trajectories. Although some corrections were proposed¹⁴⁷ these approaches are purely empirical.</p> | <p>Strengths</p> <p>Imply the location of sources or factors relative to the sampling site.</p> <p>Account for air mass transport over hundreds to thousands of kilometers and on the order of several days.</p> <p>Resolve the spatial distribution of source strength (qualitatively).</p> <p>Weaknesses</p> <p>Need to generate and analyze the back trajectory data.</p> <p>Need to correct for the central tendency and tailing effect.</p> <p>The amount of emission entrainment should not be proportional to the residence time of trajectories (so there is no linear relationship between RTWC field and source strength).</p> <p>Physical meaning of the RTWC field is unclear.</p> <p>Difficult to resolve the location of more localized sources.</p> |

A.4. Exposure Assessment

A.4.1. Exposure Assessment Study Findings

Table A-53. Exposure Assessment Study Summaries

Abou Chakra et al. (2007, [098819](#))

| | |
|------------------------------|--|
| Study Design | Experimental, in vitro. HeLa cells incubated with organic extracts of personal PM ₁₀ and PM _{2.5} samples |
| Period | NR |
| Location | 3 French metropolitan areas (Paris, Rouen, Strasbourg) with varying air quality and emission sources |
| Population | Individuals from urban areas with varying air pollution levels and emissions sources |
| Age Groups | Children ages 6-13. Ages of adults not given |
| Indoor Source | NR |
| Personal Method | Harvard multi-pollutant Chempass personal exposure sampler placed in backpacks with BGI pump operating at 1.8 l/min. |
| Personal Size | PM ₁₀ , PM _{2.5} |
| Microenvironment Size | NR |
| Ambient Size | NR |
| Component(s) | Organic extracts of PM ₁₀ , organic extracts of PM _{2.5} |
| Primary Findings | Genotoxic effects were stronger for organic extracts of PM _{2.5} than for PM ₁₀ and greater in winter than summer. Greater effects for winter samples may be attributed to elevated winter PAH concentrations. |

Abu-Allaban et al. (2004, [156187](#))

| | |
|------------------------------|--|
| Study Design | Exposure assessment of real world motor vehicle emissions |
| Period | May 18-22, 1999 |
| Location | Tuscarosa Mountain Tunnel, Pennsylvania Turnpike |
| Population | Highway tunnel |
| Age Groups | NR |
| Indoor Source | NR |
| Personal Method | No personal exposure assessment was conducted. |
| Personal Size | NR |
| Microenvironment Size | 0.01-0.5 µm |
| Ambient Size | NR |
| Component(s) | NR |
| Primary Findings | Monitoring sessions with the highest fraction heavy-duty vehicles had the highest particle concentrations; Observed particle size distribution was a combination of 2 bimodal log-normal distributions a dominant nucleation mode (86% of area under the curve). |

Adar et al. (2007, [098635](#))

| | |
|------------------------------|--|
| Study Design | Cohort |
| Period | March 2002-June 2002 |
| Location | St. Louis, Missouri |
| Population | Senior citizens exposed to traffic-related PM |
| Age Groups | 60 |
| Indoor Source | NR |
| Personal Method | Samples of FeNO were collected between 8:00 and 9:00 a.m. on the mornings before and after each trip. In the hours surrounding these samples, group-level measurements of particle concentrations also were collected using several continuous instruments installed on two portable carts. These carts were first positioned in a central location inside the participants' living facilities 24-h before each trip. The carts remained at the facilities until it was time for the trips, at which point they followed the participants from the health testing room, onto the bus, to the group activity, and to lunch. After the trip home aboard the bus, the carts were returned to the central location in the living facility where they remained until the conclusion of the health testing on the following morning. Continuous measurements of ambient particles and gases also were collected from a central monitoring station in East St. Louis, Illinois.; Specifics-; Two portable carts containing continuous air pollution monitors were used to measure group-level micro-environmental exposures to traffic related pollutants, including fine particulate mass (< 2.5 µm aerodynamic diameter; PM _{2.5}), BC, and size-specific particle counts. PM _{2.5} concentrations were measured continuously using a DustTrak aerosol monitor model 8520 with a Nafion diffusion dryer. Integrated samples of PM _{2.5} mass also were collected using a Harvard Impactor for daily calibration of the trip and facility (missing items?) |
| Periods | Continuous BC concentrations were measured using a portable aethalometer with a 2.5-µm impaction inlet. Particle counts were measured using a model CI500 optical particle counter with a modified flow rate of 0.1 cubic feet per minute. |
| Personal Size | NR |
| Microenvironment Size | PM _{2.5} |

| | |
|----------------------------------|---|
| Ambient Size Component(s) | PM _{2.5} ; PM ₁₀ BC; Pollen and Mold also assessed |
| Primary Findings | Fine particle exposures resulted in increased levels of FeNO in elderly adults, suggestive of increased airway inflammation. These associations were best assessed by microenvironmental exposure measurements during periods of high personal particle exposures. In pre-trip samples, both microenvironmental and ambient exposures to fine particles were positively associated with FeNO. For example, an interquartile increase of 4 $\mu\text{g}/\text{m}^3$ in the daily microenvironmental PM _{2.5} concentration was associated with a 13% [95% CI: 2-24] increase in FeNO. After the trips, however, FeNO concentrations were associated predominantly with microenvironmental exposures, with significant associations for concentrations measured throughout the whole day. Associations with exposures during the trip also were strong and statistically significant with a 24% (95% CI: 15-34) increase in FeNO predicted per interquartile increase of 9 $\mu\text{g}/\text{m}^3$ in PM _{2.5} . Although pre-trip findings were generally robust and the post-trip findings were generally robust, the post-trip findings were sensitive to several influential days. |

Adgate et al. (2002, [030676](#))

| | |
|------------------------------|--|
| Study Design | Comparison of outdoor, indoor and personal PM _{2.5} in three communities. |
| Period | April-June, June-August, September-November, 1999 |
| Location | Battle Creek, East St. Paul, and Phillips, Minnesota, constituting the Minneapolis-St. Paul metropolitan area. |
| Population | adults in urban areas |
| Age Groups | mean age 42 \pm 10, range 24-64 yr |
| Indoor Source | No |
| Personal Method | Inertial impactors (PEM) in a foam-insulated bag with shoulder strap with the inlet mounted on the front. |
| Personal Size | PM _{2.5} |
| Microenvironment Size | PM _{2.5} |
| Ambient Size | PM _{2.5} |
| Component(s) | NR |
| Primary Findings | The relative level of concentrations report in other studies was duplicated. Outdoor < indoor < personal. On days with paired samples (n = 29), outdoor concentrations were significantly lower (mean difference 2.9 $\mu\text{g}/\text{m}^3$, p = 0.026) than outdoor at home. |

Adgate et al. (2007, [156196](#))

| | |
|------------------------------|---|
| Study Design | NR |
| Period | 1999-; April 26-June 20, June 21-August 11, September 23-November 21 |
| Location | Minneapolis-St. Paul metropolitan area |
| Population | NR |
| Indoor Source | Cigarette smoke, resuspension of house dust from carpets, furniture and clothes, and emissions from stoves and kerosene heaters (Leaderer et al., 1993; Ferro et al., 2004). |
| Personal Method | Personal monitoring was conducted using a and consisted of two consecutive days, and was conducted so that the two 24-h averages matched indoor (I) and personal (P) measurements were collected in concert with O samples in each community. Gravimetric concentrations for P and I were collected using inertial impactor environmental monitoring inlets and air sampling pumps. To obtain I measurements, monitors were placed inside each residence in a room where the participants reported spending the most waking hours. P measurements were obtained by carrying personal pumps in small bags.; Outdoor central site samples (O) were collected near the approximate geographic center of each neighborhood and monitors ran from midnight to midnight for two consecutive 24-h periods, followed by a day to change filters. Gravimetric O PM _{2.5} concentrations were obtained using a federal reference method sampler. |
| Personal Size | PM _{2.5} -broken down into TE |
| Microenvironment Size | PM _{2.5} -broken down into TE |
| Ambient Size | PM _{2.5} -broken down into TE |
| Component(s) | Ag, Al, Ca, Cd, Co, Cr, Cs, Cu, Fe, K, La, Mg, Mn, Na, Ni, Pb, S, Sb, Sc, Ti, Tl, V, Zn |
| Primary Findings | The relationships among P, I, and O concentrations varied across TEs. Unadjusted mixed-model results demonstrated that O monitors are more likely to underestimate than overestimate exposure to many of the TEs that are suspected to play a role in the causation of air pollution related health effects. These data also support the conclusion that TE exposures are more likely to be underestimated in the lower income and centrally located PHI community than in the comparatively higher income BC K community. Within the limits of statistical power for this sample size, the adjusted models indicated clear seasonal and community related effects that should be incorporated in long-term exposure estimates for this population. |

Adgate et al. (2003, [040341](#))

| | |
|----------------------|--|
| Study Design | Time-series epidemiologic study |
| Period | April-November 1999; spring: 26 April-20 June; summer: 21 June-11 August; fall: 23 September-21 November |
| Location | Minneapolis-St. Paul, Minnesota |
| Population | Healthy non-smoking results |
| Age Groups | 24-64 yr (mean age 42 \pm 10) |
| Indoor Source | NR |

| | |
|------------------------------|--|
| Personal Method | Personal and indoor gravimetric PM concentrations were collected using PM _{2.5} inertial impactor environmental monitoring inlets and air sampling pumps. Monitors were placed inside each participant's residence in the room where he/she reported spending the majority of their waking hours to obtain indoor (I) measurements. Participants also carried personal pumps in small bags to obtain personal (P) measurements. Start times for indoor and personal monitors were always within a few minutes of each other. Gravimetric outdoor (O) and central site PM _{2.5} concentrations were obtained using a federal reference method sampler and EPA site requirements for ambient sampling. Gravimetric samples were collected near the approximate geographic center of each neighborhood, and monitors ran from midnight to midnight for 2 consecutive 24-h periods, followed by a day to change filters. |
| Personal Size | NR |
| Microenvironment Size | NR |
| Ambient Size | NR |
| Component(s) | NR |
| Primary Findings | Personal (P) PM _{2.5} concentrations were higher than indoor (I) concentrations, which were higher than outdoor (O) concentrations. In healthy non-smoking adults, moderate median PI; modest median IO; and minimal median PO longitudinal correlation coefficients were observed for PM _{2.5} measurements. A sensitivity analysis indicated that correlations did not increase if the days with exposures to environmental tobacco smoke or occupational exposures were excluded. In the sample population neither P nor I monitors provided a highly correlated estimate of exposure to O PM _{2.5} over time. These results suggest that the studies showing relatively strong longitudinal correlation coefficients between P and O PM _{2.5} for individuals sensitive to air pollution health effects do not necessarily predict exposure to PM _{2.5} in the general population. |

Alander et al. (2004, [055650](#))

| | |
|------------------------------|--|
| Study Design | Exposure assessment, characterization of effects of fuel reformulation, engine design, and exhaust after-treatment on PM emissions |
| Period | NR |
| Location | Laboratory |
| Population | Diesel-powered passenger cars of different engine types and different formulations of diesel fuel |
| Age Groups | NR |
| Indoor Source | NR |
| Personal Method | No personal exposure assessment was conducted |
| Personal Size | NR |
| Microenvironment Size | NR |
| Ambient Size | NR |
| Component(s) | Total carbon, organic carbon, elemental carbon, sulfate, nitrate, chloride |
| Primary Findings | Reformulated low sulfur diesel fuel produced 40% less total carbon mass compared to standard fuel. Organic carbon constituted 27-61% carbon mass from an indirect ignition engine. Low sulfur fuel reduced organic carbon mass by 10-55%, depending on engine. |

Allen et al. (2003, [053578](#))

| | |
|------------------------------|--|
| Study Design | Use of continuous light scattering data to separate indoor PM into indoor- and outdoor-generated components to enhance knowledge of the outdoor contribution to total indoor and personal PM exposures. |
| Period | November 1999-May 2001 |
| Location | Seattle, WA |
| Population | Elderly people and children spending most of their time (up to 70%) indoors.; The study included healthy elderly subjects, elderly with COPD and coronary heart disease (CHD), and child subjects with asthma. |
| Age Groups | Age n; 0-29 25; 30-59 36; > 60 22; unknown 2 |
| Indoor Source | Suggested (not identified) |
| Personal Method | NR. Indoor and outdoor sampling conducted |
| Personal Size | NR |
| Microenvironment Size | PM _{2.5} |
| Ambient Size | PM _{2.5} |
| Component(s) | Sulfur |
| Primary Findings | A recursive mass balance model can be successfully used to attribute indoor PM to its outdoor and indoor components and to estimate an avg P, a, k, and NH ₄ ⁺ for each residence. |

Allen et al. (2007, [154226](#))

| | |
|------------------------------|--|
| Period | Heating season October-February; Non-heating season March-September; (Year not specified) |
| Location | Seattle, WA |
| Population | NR |
| Age Groups | NR |
| Indoor Source | NR |
| Personal Method | Indoor and outdoor PM _{2.5} was measured using a 10-l/min single-stage Harvard Impactor (HI) with 37-mm Teflon filters. The relationship between particle mass concentration and light scattering coefficient (bsp) was also measured on a continuous basis indoors and outdoors using nephelometers (model 902 and 903). |
| Personal Size | NR |
| Microenvironment Size | PM _{2.5} |
| Ambient Size | PM _{2.5} |
| Component(s) | Sulfur (measured by XRF) |

Primary Findings The authors showed that RM can reliably estimate F_{inf} . Simulation results suggest that the RM F_{inf} estimates are minimally impacted by measurement error. In addition, the average light scattering response per unit mass concentration was greater indoors than outdoors. Results show that the RM method is unable to provide satisfactory estimates of the individual components of F_{inf} . Iliu et al individual homes vary in their infiltration efficiencies, thereby contributing to exposure misclassification in epidemiologic studies that assign exposures using ambient monitoring data. This variation across homes indicates the need for home-specific estimation methods, such as RM or sulfur tracer, instead of techniques that give average estimates of infiltration across homes.

Allen et al. (2007, [156207](#))

Study Design Primarily a study of exposure to indoor PBDE congeners.
Period Jan-Mar 2006
Location Greater Boston area, Massachusetts
Population Urban dwellers
Age Groups NR
Indoor Source NR
Personal Method No particulate sampled
Personal Size No particulate sampled
Microenvironment Size No particulate sampled
Component(s) Polybrominated diphenyls (PBDEs), divided into 13 congeners and total BDE (SBDE), which includes both vapor and particulate phase.
Primary Findings Total personal air concentrations (particulate \pm vapor) were 469 pg/m³ for non-209 BDEs and 174 pg/m³ for BDE 209, significantly higher than bedroom and main living room concentrations ($p = 0.01$). The ratio of personal air to room air increased from 1 for vapor-phase congeners to 4 for fully particulate-bound congeners, indicating a personal cloud effect.

Andresen et al. (2005, [156216](#))

Study Design Residential exposure assessment personal and indoor
Period June-July 2002 to December 2002
Location Mysore, India
Population Women working at home, non-smoking, and primary household cook
Age Groups 18-50 yr old
Indoor Source Cooking fuel source
Personal Method PM_{2.5} gravimetric filter measurement
Personal Size PM_{2.5}
Microenvironment Size NR
Ambient Size NR
Component(s) NR
Primary Findings Using kerosene for cooking was associated with higher personal PM_{2.5} exposure in both winter and summer compared to LPG.; Kerosene use during winter was associated with higher personal PM_{2.5} compared to summer.; LPG use was associated with comparable personal PM_{2.5} across both seasons.; Indoor PM_{2.5} measurements followed similar patterns by fuel-type and season.; Socioeconomic status, age, season, and income were significant predictors of cooking fuel choice.

Annesi-Maesano et al. (2007, [093180](#))

Study Design Population based
Period March 1999 to October 2000
Location Bordeaux, France; Clermont-Ferrand, France; Créteil, France; Marseille, France; Strasbourg, France; Reims, France
Population School children
Age Groups 10.4 \pm 0.7 yr
Indoor Source NR
Personal Method PM_{2.5} was monitored simultaneously in both schoolyards (proximity level) and fixed-site monitoring stations (city level) using 4L/min battery operated pumps attached to polyethylene filter sampling cartridges.
Personal Size NR
Microenvironment Size NR
Ambient Size PM_{2.5}
Component(s) NR
Primary Findings Results show an increased risk for EIB and flexural dermatitis at the period of the survey, past year atopic asthma and SPT positivity to indoor allergens in children exposed to high levels of traffic-related air pollution (PM_{2.5} concentrations exceeding 10 μ g/m³). Population based findings are also consistent with experimental data that have demonstrated that inhalation of traffic-related air pollutants either individually or in combination, can enhance the immune responses and airway response to inhaled allergens, such as pollens or house dust mites, in atopic subjects.

Balakrishnan et al. (2002, [156247](#))

Study Design Exposure assessment
Period July-December 1999 (20 weeks)
Location 50 villages, Tamil Nadu, India
Population Men and women in rural households; children exempt

| | |
|------------------------------|---|
| Age Groups | All, children exempt |
| Indoor Source | Yes |
| Personal Method | Personal sampler for cooks during cooking time |
| Personal Size | Respirable Particulates (based on NIOSH protocol) |
| Microenvironment Size | Respirable Particulates (based on NIOSH protocol) |
| Ambient Size | Respirable Particulates (based on NIOSH protocol) |
| Component(s) | NR |
| Primary Findings | Fuel type, type and location of the kitchen, and the time spent near the kitchen while cooking are the most important determinants of exposure across rural households. |

Balasubramanian and Lee (2007, [156248](#))

| | |
|------------------------------|---|
| Study Design | Case study of 3 rooms of 1 flat on the 8th floor, and "outside the home." |
| Period | May 12-23, 2004 |
| Location | Singapore |
| Population | Residents of an urban area in a densely populated country. |
| Age Groups | NR |
| Indoor Source | Time-activity logs identified tobacco smoking, cooking, household cleaning and general resident movements. |
| Personal Method | NR |
| Personal Size | NR |
| Microenvironment Size | PM _{2.5} |
| Ambient Size | PM _{2.5} |
| Primary Findings | Indoor/outdoor ratios (I/O) suggest that chemicals such as chloride, sodium aluminum, cobalt, copper, iron, manganese, titanium vanadium, zinc, elemental carbon were derived from the migration of outdoor particles (I/O < 1 or ~ 1). |

Barn et al. (2008, [156252](#))

| | |
|------------------------------|--|
| Study Design | Measure indoor infiltration factor (FiaC) of PM _{2.5} from forest fires/wood smoke, effectiveness of high-efficiency particulate air (HEPA) filter air cleaners in reducing indoor PM _{2.5} , and to analyze the home determinants of Fia and air cleaner effectiveness (ACE). |
| Period | 2004-2005 (summer 2004 and 2005, winter 2004) |
| Location | British Columbia, Canada |
| Population | homes affected by either forest fire smoke or residential wood smoke |
| Age Groups | NR |
| Indoor Source | NR |
| Personal Method | Pdr (Personal Data Ram) for ambient air sampling |
| Personal Size | Indoor home PM _{2.5} |
| Microenvironment Size | NR |
| Ambient Size | Outdoor home PM _{2.5} |
| Component(s) | NR |
| Primary Findings | Use of HEPA filter air cleaners can dramatically reduce indoor PM _{2.5} concentrations. Number of windows and season predict indoor infiltration Fia (p < 0.001). |

Baxter et al. (2007, [092726](#))

| | |
|------------------------------|--|
| Study Design | Part of a prospective birth cohort study performed by the Asthma Coalition for Community, Environment, and Social Stress (ACCESS) |
| Period | 2003-2005. Non-heating season- May to October; Heating season- December to March |
| Location | Boston (urban) |
| Population | Lower socio-economic status (SES) households |
| Age Groups | NR |
| Indoor Source | NR |
| Personal Method | PM _{2.5} samples were collected with Harvard personal environmental monitors (PEM).; NO concentrations were measured using Yanagisawa passive filter badges. |
| Personal Size | NR |
| Microenvironment Size | PM _{2.5} |
| Ambient Size | PM _{2.5} |
| Component(s) | EC |
| Primary Findings | The authors' regression models indicated that PM _{2.5} was influenced less by local traffic but had significant indoor sources, while EC was associated with local traffic and NO ₂ was associated with both traffic and indoor sources. However, local traffic was found to be a larger contributor to indoor NO ₂ where traffic density is high and windows are opened, whereas indoor sources are a larger contributor when traffic density is low or windows are closed. Similarly, traffic contributed up to 0.2 mg/m ³ to indoor EC for homes with open windows, with an insignificant contribution for homes where windows were closed.; Comparing models based on p-values and using a Bayesian approach yielded similar results, with traffic density volume within a 50m buffer of a home and distance from a designated truck route as important contributors to indoor levels of NO ₂ and EC, respectively. However, results from the Bayesian approach also suggested a high degree of uncertainty in selecting the best model. The authors concluded that by utilizing public databases and focused questionnaire data they could identify important predictors of indoor concentrations for multiple air pollutants in a high-risk population. |

Baxter et al. (2007, [092725](#))

| | |
|------------------------------|--|
| Study Design | Simultaneous indoor and outdoor samples taken in 43 low SES homes in heating and non-heating seasons. Homes were selected from a prospective birth cohort study of asthma etiology (n = 25). Non-cohort homes were in similar neighborhoods (n = 18). |
| Period | 2003-2005 |
| Location | Boston, Massachusetts |
| Population | Lower SES populations in urban areas |
| Indoor Source | Home type, year built, tobacco smoke, opening windows, time spent cooking, use of candles or air freshener, cleaning activities, air conditioner use. |
| Personal Method | NR |
| Personal Size | NR |
| Microenvironment Size | PM _{2.5} |
| Ambient Size | NR |
| Component(s) | EC (m ⁻¹ x 10 ⁻⁵); Ca (ng/m ³); Fe (ng/m ³); K (ng/m ³); Si (ng/m ³); Na (ng/m ³); Cl (ng/m ³); Zn (ng/m ³); S (ng/m ³); V (ng/m ³) |
| Copollutant(s) | NO ₂ |
| Primary Findings | The effect of Indoor Sources may be more pronounced in high-density multi-unit dwellings. Cooking times, gas stoves, occupant density and humidifiers contributed to indoor pollutants. |

| Ambient Size | NR |
| Component(s) | NR |
| Primary Findings | There are greater masses of PM ₁₀ indoors, and that the composition of the indoor PM ₁₀ is controlled by outdoor sources and to a lesser extent by indoor anthropogenic activities, except in the presence of tobacco smokers. The indoor and outdoor PM ₁₀ collected was characterized as being a heterogeneous mixture of particles (soot, fibers, sea salt, smelter, gypsum, pollen and fungal spores). |

| | |
|-----------------------|---|
| Study Design | This is an evaluation of the active-flow pDR for PM _{2.5} against the □ Attenuation Monitor (BAM) and the gravimetric pDR |
| Period | NR |
| Location | Los Angeles, California |
| Population | NR |
| Age Groups | NR |
| Indoor Source | NR |
| Personal Method | NR |
| Personal Size | NR |
| Microenvironment Size | NR |
| Ambient Size | PM _{2.5} |
| Component(s) | NR |
| Primary Findings | The personal pDR can be deployed as a personal monitor. The PM _{2.5} cyclone prevents larger particles from biasing the results. Along with a wearable humidity and temperature monitor for correcting the readings, the results correlate highly with other methods. The samples can be taken every 15 min to provide a more accurate picture of personal exposure in various settings. |

Chang et al. (2007, [156331](#))

| | |
|--------------|-----------------------|
| Study Design | Panel study |
| Period | 2003 to 2005 |
| Location | Taipei County, Taipei |
| Population | Elderly people |

| | |
|------------------------------|---|
| Age Groups | 53-75yr (median = 66.2 ± 6.5) |
| Indoor Source | NR |
| Personal Method | Personal exposures to PM were measured simultaneously with ECG in real-time for twenty-four hours by using a personal dust monitor (DUSTcheck portable dust monitor, model 1.108) which recorded 1-min mass concentrations of PM ₁ , PM _{2.5} , and PM ₁₀ , as well as ambient temperature and relative humidity. To measure subjects' personal PM exposures, all subjects were instructed to keep the DUSTcheck monitor with them at all times.; Details were reported previously (Chuang et al. 2005) |
| Personal Size | PM ₁₀ ; PM _{2.5-10} ; PM _{2.5} ; PM _{1-2.5} ; PM ₁ |
| Microenvironment Size | NR |
| Ambient Size | NR |
| Component(s) | NR |
| Primary Findings | Short-term and medium-term PM exposures were associated with the reduction of HRV in the elderly, with stronger effects found for coarse particles in comparison with particles of other size ranges. In general, increase was observed with PM for H and the LF/HF ratio, where the strongest significant effects on H were found at short-term intervals (1-4 h) for PM _{2.5-10} and at medium-term duration (5-8 h) for particles smaller than 2.5 μm in diameter. On the other hand, among the different-sized particles, PM _{2.5-10} exposures showed the strongest significant association with decreases in time-domain (SDNN, r- MSSD) and frequency-domain parameters (LF, HF) in most averaging Periods. Especially for the longer duration of 5-8 h, the strongest association was found for the 6-h moving average of PM _{2.5-10} exposures. |

|------------------------------|--|
| Study Design | Repeated measures on a cohort of high school students in New York City |
| Period | Summer and winter of 1999 (eight weeks each) |
| Location | Manhattan, Bronx, Queens, Brooklyn, NY |
| Population | Persons traveling the subway |
| Age Groups | 14-18 yr |
| Indoor Source | No |
| Personal Method | Sampling packs carried by subjects |
| Personal Size | PM _{2.5} |
| Microenvironment Size | PM _{2.5} ; Home indoor and home outdoor |
| Ambient Size | PM _{2.5} . Urban fixed-site and upwind fixed site operated for three consecutive 48-h periods each week. |
| Component(s) | Elemental iron, manganese, and chromium are reported in this study out of 28 elements sampled. |
| Primary Findings | Personal samples had significantly higher concentration of iron, manganese, and chromium than home indoor and ambient samples. The ratios of Fe (ng/μg of PM _{2.5}) vs Mn (pg/μg PM _{2.5}) showed personal samples to be twice the ratio for crustal material. Similarly for the Cr/Mn ratio. The ratios and strong correlations between pairs of elements suggested steel dust as the source. Time-activity data suggested subways as a source of the elevated personal metal levels. |

|------------------------------|--|
| Study Design | Exposure assessment. Sampling of schools, residence, private vehicle |
| Period | Schools- 11/2003-02/2004 and 10/2004-12/2004.; Residence- 10/2004; Vehicle- 10/204-12/2004 |
| Location | Athens, Greece |
| Population | Primary school children |
| Age Groups | NR |
| Indoor Source | NR |
| Personal Method | Handheld portable Condensation Particle Counters (TSI, Model 3007) were used for all sampling locations. Primary schools indoor measurements were primarily conducted inside classrooms, at table height. However, at three of the schools, rooms of different uses were selected. These included a teachers' office (where smoking was permitted), a computer day lab (used by students only part of the day), and a library and gymnasium (where intense activity took place almost all day long). Outdoor measurements took place in the yard of each school. Residence samples were taken in a bedroom at breathing height and on the terrace, for indoor and outdoor samples, respectively. In-vehicle samples were taken by placing the CPC 3700 on the passenger seat while the vehicle drove along predetermined routes. |
| Personal Size | NR |
| Microenvironment Size | 0.01-1 µm |
| Ambient Size | 0.01-1 µm |
| Component(s) | NR |
| Primary Findings | The results showed that children attending primary schools in the Athens area are exposed to significant PM concentration levels, both indoors and outdoors. Vehicular emissions seem to be a major contributor to the measured outdoor concentration levels at the studied sites. Indoor PM concentrations appeared to be influenced by both vehicular emissions and indoor sources including |

cleaning activities, smoking, a high number of people in relation to room volume and furniture material (i.e., carpet.); UFPs concentrations diurnal variation, both outside the schools and the residence, supports the close relation of UFPs levels with traffic density. Indoor concentrations within schools exhibited variability during the school day only when there were significant changes in room occupancy. 24-h variation of indoor concentrations at the residence followed quite well ($R^2 = 0.89$) the outdoor one, with a delay of 1-h or less.

| Study Design | Molecular epidemiology studies of carcinogenic environmental pollutants, particularly PAHs |
| Period | NR |
| Location | Prague, Czech Rep.; Kosice, Slovak Rep.; Sofia, Bulgaria |
| Population | Policemen and bus drivers |
| Age Groups | NR |
| Indoor Source | No |
| Personal Method | "Personal monitors for PM ₁₀ "; Extraction by dichloromethane and analyzed for PAH by HPLC with fluorimetric detection. |
| Personal Size | PM ₁₀ |
| Microenvironment Size | NR |
| Ambient Size | PM ₁₀ ; Extractable organic material (EOM); B[a]P; cPAHs |
| Component(s) | Benzo[a]pyrene (B[a]P); Carcinogenic polycyclic aromatic hydrocarbons (cPAHs) |
| Primary Findings | Personal exposure to B[a]P and to total carcinogenic PAHs in Prague was twofold higher in the exposed group compared to controls, in Kosice three fold higher, and in Sofia 2.5-fold higher. |

Ferro et al. (2004, [055387](#))

| | |
|------------------------------|---|
| Study Design | Case study, 1 home |
| Period | Redwood City, California |
| Location | NR |
| Population | NR |
| Age Groups | NR |
| Personal Method | Co-located real-time particle counters and integrated filter samplers (Met-One Model 237B) were used to measure personal (PEM), indoor (SIM) and outdoor (SAM) PM concentrations. The PEM was attached to a backpack frame and worn by the investigator while performing prescribed activities. The SIM was attached to a six foot step-ladder with the intake at breathing height. The SAM was located under a two-sided roofed shed in the backyard of the home with the filter samplers supported by a metal stand and the real-time particle counters sitting on a table. |
| Personal Size | PM ₅ |
| Microenvironment Size | PM _{2.5} ; PM ₅ |
| Ambient Size | PM _{2.5} ; PM ₅ |
| Component(s) | NR |
| Primary Findings | The results of this study indicate that house dust resuspended from a range of human activities increases personal PM concentrations and this resuspension effect significantly contributes to the personal cloud. The results of this study also suggest that normal human activities that resuspend house dust may contribute significantly to the strong correlations found between personal exposure and indoor PM concentrations in previous studies. The PEM/SIM ratios for human activity presented in this paper are also in the range of those reported by previous studies. |

Ferro et al. (2004, [055676](#))

| | |
|------------------------------|---|
| Study Design | Modeling of PM source strengths from human activities |
| Period | April 2000 |
| Location | Redwood City, CA |
| Population | Residential home occupants |
| Age Groups | NR |
| Indoor Source | Yes. Vacuuming resulted in the maximum PM _{2.5} source strength while two persons walking around and sitting on furniture resulted in the maximum PM ₅ source strength. |
| Personal Method | Met-One Model 237B laser particle counters (2.8 Lpm); AIHL design cyclone samplers with filters (21 and 11 Lpm for PM _{2.5} and PM ₅ respectively) |
| Personal Size | PM _{2.5} , PM ₅ |
| Microenvironment Size | PM _{2.5} , PM ₅ |
| Ambient Size | PM _{2.5} , PM ₅ |
| Component(s) | NR |
| Primary Findings | The source strengths were found to be a function of the number of persons performing the activity, the vigor of the activity, and the type of flooring. Proximity to the source played a large role in the observed differences between indoor concentration and personal exposure. |

Fromme et al. (2007, [156453](#))

| | |
|------------------------------|--|
| Study Design | Explorative analysis |
| Period | Winter session December 2004-March 2005; summer session May to July 2005 |
| Location | Munich (and surrounding districts), Germany |
| Population | Primary and secondary school children |
| Age Groups | NR |
| Indoor Source | NR |
| Personal Method | Filter-based measurements of PM _{2.5} in the classrooms were conducted with a medium volume sampler using a flow controlled pump (Derenda, Teltow, Germany). The sample inlet was a PM _{2.5} sampler, having a 50% collection efficiency for particles with a 2.5 mm aerodynamic diameter. A Munktell 47mm binder free glass fibre filter with a pore size of 2 mm was used. Continuous measurements of PM (e.g. PM ₁₀ , PM ₄ , PM _{2.5}) were also done using an optical laser aerosol spectrometer (LAS) (Dust monitor 1.108). A TSI model 3034 scanning mobility particle sizer (SMPS) (TSI Inc., Shoreview, MN, USA) was used to measure particle number concentrations (PNC) for a discrete size distribution of aerosols. Indoor carbon dioxide was measured using a continuously monitoring infrared sensor (Testo 445).; The sampling and measuring position in the classroom was opposite to the black board, about one meter above floor level, the level at which the pupils would normally inhale. |
| Personal Size | NR |
| Microenvironment Size | PM _{2.5} ; PM ₄ ; PM ₁₀ |
| Ambient Size | PM ₁₀ , PN (particle number) |
| Copollutant(s) | CO ₂ |
| Primary Findings | Results clearly showed that exposure to PM in school is high. This study identified parameters correlated with increased concentrations of PM such as high CO ₂ concentrations and low class level. Strong seasonal variability was observed, with air quality being particularly poor in winter. The influence of season on PM concentrations observed has been reported before from the US (Keeler et al., 2002). This difference is most likely due to the different ventilation practice in summer and winter. Further parameters correlated with increased concentrations of PM were small room size, high number of occupants, high CO ₂ concentrations and low class level. No significant differences between PM and values in classrooms with carpets and those with hard surface floorings were reported. The number of fine and ultra fine particles measured in classrooms was in the same range or lower as the results from residences or outdoor monitoring sites (reported in similar studies) and show little variation. |

| Study Design | Fine particle exposure assessment for children in French urban environments, part of VESTA study |
| Period | March 1998-December 2000 |
| Location | Paris, Grenoble, Toulouse, France |
| Population | Children aged 8-14 yr |
| Indoor Source | Yes-ETS from mother, rodents at home. |
| Personal Method | SKC pump 4 Lpm with PM _{2.5} inlet and 37 mm, 2 micron Teflon filter |
| Personal Size | PM _{2.5} |
| Microenvironment Size | NR |
| Ambient Size | PM ₁₀ |
| Component(s) | NR |
| Primary Findings | The final model explains 36% of the between subjects variance in PM _{2.5} exposure, with ETS contributing more than a third to this. |

Geyh et al. (2004, [156467](#))

| | |
|------------------------------|--|
| Study Design | An evaluation of a modified personal monitoring pump (PMASS) |
| Period | NR |
| Location | Fresno, CA and Baltimore, Maryland |
| Population | Persons for personal sampling |
| Age Groups | NR |
| Indoor Source | PMASS and PEM "adjusted mass measurements downward by 22% to eliminate measurement bias with the Harvard impactor." |
| Personal Method | Particle mass |
| Personal Size | Particle mass |
| Microenvironment Size | NR |
| Ambient Size | EC, OC, nitrate |
| Primary Finding(s) | PMASS measurements of mass showed a significant bias of -24% compared to the reference sampler.; For microenvironmental sampling the PMASS for mass concentrations again had a bias of -34%, but for EC, OC and nitrate were much closer but still with a bias of 6.6-17.5%. |

Geyh et al. (2005, [186949](#))

| | |
|------------------------------|--|
| Study Design | Exposure assessment- representative population (WTC truck drivers) study |
| Period | October 2001 and April 2002 |
| Indoor Source | Indoor |
| Personal Method | Each driver was given two monitors consisting of small portable pumps and battery packs worn at the waist, and sampling cartridges worn on the shoulder within the breathing zone. Monitoring was conducted across a work shift on all days of the week during both day and night shifts (6:00am to 6:00pm, and 6:00pm to 6:00am, respectively). Drivers were asked to wear their monitors at all times. If they were planning to sleep in their trucks, they were told they could remove the pumps from their belts and place them on the seat beside them.; Area monitoring was also conducted at the site at four locations around the perimeter of the disaster site on streets approximately representing the north, east, and south/southwest boundaries of the debris field. In addition, monitoring was also conducted directly in the debris pile for several days. The set of monitors were hung at head height either from scaffolding, from a chain link fence, or placed on supports, such as tank cages in the debris pile.; Sampling pumps used for particle sampling were either SKC Universal pumps(model 223-PCXR4), BGI personal sampling pumps (model 400S0, or ELF personal sampling pumps (MSA Inc). VOC sampling was conducted with SKC pocket pumps (Personal Packet Pump 210 series). |
| Personal Size | TD; PM ₁₀ ; PM _{2.5} |
| Microenvironment Size | NR |
| Ambient Size | TD; PM ₁₀ ; PM _{2.5} |
| Component(s) | EC; OC |
| Copollutant(s) | VOC(s) |
| Primary Findings | During October, the median personal exposure to TD was 346 µg/m ³ . The maximum area concentration 1742 µg/m ³ , was found in the middle of the debris. The maximum TD concentration found at the perimeter was 392 µg/m ³ implying a strong concentration gradient from the middle of debris outward. PM _{2.5} /PM ₁₀ ratios ranged from 23% to 100% suggesting significant fire activity during some of the sampled shifts. During April, the median personal exposure to TD was 144 µg/m ³ , and the highest area concentration, 195 µg/m ³ , was found at the perimeter. Although the overall concentrations on PM at the site were significantly lower in April, the relative contributions of fine particles to the PM ₁₀ , and EC and OC to the TD were similar. During both months, volatile organic compounds concentrations were low. Comparison of recorded EC and OC values from October 2001 and April 2002 with previous studies suggests that the primary source of exposure to EC for the WTC truck drivers was emissions from their own vehicles. |

Goyal and Sidhartha (2004, [156487](#))

| | |
|----------------------|---|
| Study Design | Actual air monitoring measurements are compared with a model. |
| Period | 1998-1999 |
| Location | Delhi, India |
| Population | Residents near coal-fired power plants (BTPS) |
| Age Groups | NR |
| Indoor Source | NR |

| | |
|------------------------------|---|
| Personal Method | NR |
| Personal Size | NR |
| Microenvironment Size | NR |
| Ambient Size | Suspended PM (SPM) |
| Component(s) | NR |
| Primary Findings | Measured SPM values are higher during the day than at night. This is because "point sources dominate during the daytime convective conditions. At night the small depth of the nocturnal boundary layer prevents the dispersion of the pollutants from the elevated point source to reach the surface. Convective turbulence breaks up the surface-based inversion and the fumigation process leads to an increased contribution from the point sources." |

| | |
|---------------------|---------------------------|
| Study Design | Human exposure assessment |
|---------------------|---------------------------|

| | |
|------------------------------|--|
| Period | 25 Sept. 2002 to 8 March 2003 |
| Location | Hong Kong |
| Population | Occupied buildings located near major roadways |
| Age Groups | NR |
| Indoor Source | Yes. Regression of indoor versus outdoor concentrations of OC and EC revealed an indoor source of OC not present for EC, presumably due to such activities of cooking, smoking, and cleaning. |
| Personal Method | Co-located mini-volume samplers (flow rate 5 L/min) and Partisol model 2000 sampler with 2.5 micron inlet. All samples on 47 mm Whatman quartz microfiber filters, weighed on an electronic microbalance. Analyzed for OC and EC using DRI Model 2001 Thermal/Optical Carbon Analyzer. |
| Personal Size | PM _{2.5} |
| Microenvironment Size | NR |
| Ambient Size | PM _{2.5} |
| Component(s) | OC; EC; OM; TCA |
| Primary Findings | The major source of indoor EC, OC, and PM _{2.5} appears to be penetration of outdoor air, with a much greater attenuation in mechanically ventilated buildings. |

Hoek et al. (2008, [156554](#))

| | |
|------------------------------|---|
| Study Design | Exposure assessment, characterizing indoor/outdoor particle relationships |
| Period | October 2002-March 2004 |
| Location | 4 European cities Amsterdam, Athens, Birmingham, Helsinki |
| Population | Urban populations |
| Age Groups | NR |
| Indoor Source | Smoking, candle burning, cooking/frying |
| Personal Method | No personal exposure assessment was conducted |
| Personal Size | NR |
| Microenvironment Size | PM ₁₀ , PM _{2.5} , PM _{10-2.5} , Ultrafine (UFP) |
| Ambient Size | PM ₁₀ , PM _{2.5} , PM _{10-2.5} , Ultrafine (UFP) |
| Component(s) | soot, sulfate |
| Primary Findings | Correlation between 24-avg [should this be 24-h avg?] central site and indoor concentrations was lower for UFP than for PM _{2.5} , soot, or sulfate, probably related to greater losses during infiltration due to smaller particle size. Infiltration factors for UFP and PM _{2.5} were low. |

|------------------------------|---|
| Study Design | Longitudinal analysis (repeated measures) of local PM _{2.5} and biological markers of cardiovascular dysregulation |
| Period | 3 months (Feb 8-Apr 30, 2000) |
| Location | Mexico City, Mexico |
| Population | Elderly residents of a nursing home (non-smokers) |
| Age Groups | 60-96 |
| Indoor Source | Sources of indoor PM concentrations may be idling buses parked for a few hours close to living areas at least 3 times per week |
| Personal Method | Mini-vol portable air samplers operating at 4 l/min used to monitor outdoor and indoor PM _{2.5} concentrations at a nursing home. Gravimetric analysis of filters. Personal exposure calculated using time-weighted averages of outdoor and indoor concentration |
| Personal Size | NR |
| Microenvironment Size | NR |
| Ambient Size | NR |
| Component(s) | NR |
| Primary Findings | Increases in personal PM _{2.5} concentrations were associated with significant decreases in the high-frequency component of heart rate variability (HRV-hF) among elderly. Associations remained significant after adjusting for ozone; Indoor and outdoor PM _{2.5} |

Hopke et al. (2003, [095544](#))

| | |
|------------------------|---|
| Study Design | Epidemiology-Exposure study |
| Period | 26 July to 22 August 1998 |
| Location | Retirement facility in Towson, MD |
| Population | "A potentially susceptible elderly subpopulation" |
| Age Groups | Mean age of 84 |
| Indoor Source | Ammonium sulfate and ammonium nitrate, secondary sulfate, OC, and motor vehicle exhaust |
| Personal Method | Personal exposure samples were collected on 37mm Teflon filters using inertial impactor PEM in the breathing zone of the subjects. A "scalper" (MSP, PEM-019) nozzle was used on the PEM to exclude particles >4mm in order to reduce the potential of overloading the impactor. Centralized indoor sampling was conducted in an unoccupied apartment on the fifth floor of the retirement facility (central indoor). The windows of the apartment were kept closed and the front door was kept open to the common hallway with a small fan providing active air exchange. Residential outdoor sampling at the retirement facility was conducted from the rooftop of an attached three-story nursing care facility (outdoor). PM _{2.5} measurements at an ambient site in Towson, MD were made on the roof of a sampling shelter approximately four meters off the ground (community). Daily community, outdoor, and central indoor PM _{2.5} samples were collected with VAPS samplers. |
| Personal Size | PM _{2.5} |

| | |
|------------------------------|--|
| Microenvironment Size | PM _{2.5} |
| Ambient Size | PM _{2.5} |
| Component(s) | NR |
| Primary Findings | VAPS and PEM data from the BPMEES were separately analyzed by different receptor models. These two approaches were complementary and allowed for evaluation of all of the available data. A three-way analysis of the VAPS data provided four sources of PM _{2.5} , nitrate-sulfate, sulfate, OC, and MV exhaust. The largest contribution to the community, outdoor, and central indoor sampling locations was the sulfate source. Infiltration of the sources varied depending on the source and ranged from 38% to 4% for the Sulfate, and Nitrate-Sulfate sources, respectively. In addition, MV exhaust had a penetration rate similar to Sulfate (32%). The OC source had little variability compared to the other sources and contributed approximately 8% of the community and outdoor PM and 18% of the central indoor PM.; The PEM data were analyzed using a complex model with a target for soil that included factors that are common to all of the types of samples (external factors) and factors that only apply to the data from the individual and apartment samples (internal factors). From these results, the impact of outdoor sources and indoor sources on indoor concentrations were assessed. The identified external factors were sulfate, soil, and an unknown factor. Internal factors were identified as gypsum or wall board, personal care products, and a factor representing variability not explained by the other indoor sources. The latter factor had a composition similar to outdoor particulate matter and explained 36% of the personal exposure. External factors contributed 63% to personal exposure with the largest contribution from sulfate (48%). |

| Age Groups | 71-86 yr |
| Indoor Source | No |
| Personal Method | Personal PM ₁₀ MPEM10; Indoor home and Outdoor home PM _{2.5} , PM ₁₀ Single-stage inertial Harvard Impactors and 37-mm Teflon filters |
| Personal Size | PM ₁₀ |
| Microenvironment Size | PM ₁₀ , PM _{2.5} , fine particles (~PM1) |
| Ambient Size | PM ₁₀ , PM _{2.5} |

Component(s) BC, as an estimate of elemental carbon (EC)
Primary Findings For 7 subjects with asthma, a 10 µg/m³ increase in 24-h avg outdoor PM₁₀; and PM_{2.5} was associated with a 5.9 [95% CI: 2.9-8.9] and 4.2 ppb (95% CI: 1.3-7.1) increase in FeNO, respectively. A 1 µg/m³ increase in outdoor, indoor, and personal BC was associated with increases in FeNO of 2.3 ppb (95% CI: 1.1-3.6), 4.0 ppb (95% CI: 2.0-5.9), and 1.2 ppb (95% CI: 0.2-2.2), respectively. No significant association was found between; PM or BC measures and changes in spirometry, blood pressure, pulse rate, or SaO₂ in these subjects.

Jaques et al. (2004, [155878](#))

Study Design Exposure assessment, field evaluation of continuous PM_{2.5} monitor in comparison to integrated samplers
Period February-August 2002
Location Claremont, California
Population Continuous PM_{2.5} sampler, time-integrated PM_{2.5} samplers
Age Groups NR
Indoor Source NR
Personal Method No personal exposure assessment was conducted
Personal Size NR
Microenvironment Size NR
Ambient Size PM_{2.5}
Component(s) NR
Primary Findings PM_{2.5} mass measurements using the Differential TEOM monitor are consistent with those of the MOUDI and Partisol. Differences can be explained by loss of ammonium nitrate from reference time-integrated samplers. Partisol underestimates MOUDI measured mass.

Jedrychowski et al. (2006, [156606](#))

Study Design Prospective cohort
Period 11/2000-3/2003
Location Krakow, Poland
Population Non-smoking pregnant women
Age Groups Yes
Personal Method Personal; Exposure Monitor Sampler (PEMS, Harvard; School of Public Health) with
Personal Size PM_{2.5}
Microenvironment Size NR
Ambient Size PM₁₀
Component(s) NR
Primary Findings The contribution of the background ambient PM₁₀ level was very strong determinant of the total personal exposure to PM_{2.5} and it explained about 31% of variance between the subjects.

Jo and Lee (2006, [156613](#))

Study Design Case study
Period Winter of 2004 and summer of 2005
Location Daegu, Korea
Population Residents of high-rise apartment buildings
Age Groups NR
Indoor Source All of the surveyed apartments were constructed with concrete and iron frames. The apartments used liquid petroleum gas for cooking and as their primary heating system. The exhaust gas generated from heating or cooking was mechanically vented out of the apartments.
Personal Method The PM₁₀ concentrations were measured using real-time light scattering PM₁₀ monitors (HAZDUST Model EPAM-500). The CO concentrations were measured using a CO dosimeter (CMCD-10P) equipped with an activated charcoal-Purafil prefilter.; From each building, one lower-floor apartment (first or second floor) and one higher-floor apartment (between 10th and 15th floor) were simultaneously surveyed. The concentrations of CO and PM₁₀ were measured at the breathing height in the main living area where the participants spent most of their time and from the apartment balconies outdoors.
Personal Size NR
Microenvironment Size PM₁₀
Ambient Size PM₁₀
Component(s) CO
Primary Findings This study found that the outdoor air concentrations of CO and PM₁₀ were higher for lower-floor apartments than for higher-floor apartments situated in residential areas. In addition, the concentrations were significantly higher in winter and in summer, regardless of the floor height of the apartments. The indoor concentrations in the lower- and higher-floor apartments, however, were not consistent with the outdoor concentrations. Proximity to a major roadway was found to increase the indoor and outdoor concentrations of PM₁₀ in high-rise apartments and therefore cause elevated exposures of the residents during presence at home. This was not observed for CO. Atmospheric stability was found to elevate indoor and outdoor air pollutant concentrations and was therefore determined to be another important factor regarding the level of exposure to CO and PM₁₀.

|------------------------------|--|
| Study Design | Cohort |
| Period | Spring and fall seasons of 2002 and 2003 |
| Location | Gothenburg, Sweden |
| Population | General adult population |
| Age Groups | 23-51 yr |
| Indoor Source | NR |
| Personal Method | Fine particles were measured for 24 h using both personal and stationary monitoring equipment. Personal monitoring of PM _{2.5} and PM ₁ was carried out simultaneously with parallel measurements of PM _{2.5} and PM ₁ indoors in living rooms and outside the house on a balcony, porch, etc. In addition, urban background PM _{2.5} levels were measured. Personal monitoring was performed in two ways. The 20 randomly selected subjects carried personal monitoring equipment for PM _{2.5} only, while the 10 staff members carried two pieces of personal monitoring equipment at the same time. On the first measuring occasion, the staff members carried one PM _{2.5} cyclone and one PM ₁ cyclone. On the second occasion, duplicate monitors for PM _{2.5} were used. For personal and residential monitoring, the BGI Personal Sampling Pump was used together with the GK2.05 cyclone for PM _{2.5} sampling and the Triplex cyclone SCC1.062 for PM ₁ sampling. The personal sampling pump was placed in a small shoulder bag and the cyclone attached to the shoulder strap near the subject's breathing zone. The personal monitoring equipment was carried by the subject during awake time. During the night, it was placed in the living room. For indoor monitoring in living rooms, cyclones (PM _{2.5} and PM ₁) were placed at about 1.5 m above the floor. The same setup was used for residential outdoor monitoring. The urban background monitor was placed on top of a roof somewhat south of the city center but not near any major highway. |
| Personal Size | PM _{2.5} ; PM ₁ |
| Microenvironment Size | PM _{2.5} ; PM ₁ |
| Ambient Size | PM _{2.5} ; PM ₁ |
| Component(s) | BS |
| Primary Findings | Personal exposure of PM _{2.5} correlated well with indoor levels, and the associations with residential outdoor and urban background concentrations were also acceptable. Statistically significantly higher personal exposure compared with residential outdoor levels of PM _{2.5} was found for nonsmokers. PM ₁ made up a considerable proportion (about 70–80%) of PM _{2.5} . For BS, significantly higher levels were found outdoors compared with indoors, and levels were higher outdoors during the fall than during spring. There were relatively low correlations between particle mass and BS. The urban background station provided a good estimate of the residential outdoor concentrations of both PM _{2.5} and BS _{2.5} within the city. The air mass origin affected the outdoor levels of both PM _{2.5} and BS _{2.5} ; however, no effect was seen on personal exposure or indoor levels. |

| Age Groups | NR |
| Indoor Source | NR |
| Personal Method | No personal monitoring. |
| Personal Size | NR |
| Microenvironment Size | NR |
| Ambient Size | PM ₁₀ |
| Component(s) | NaCl; Strongly bound H ₂ O; Secondary organic material |
| Primary Findings | Using existing co-located and coincident data it has been possible to show that the removal of three natural components—sea salt (NaCl), strongly bound water and secondary organic matter—would reduce the number of days on which the PM ₁₀ concentration exceeds 50 µg/m ³ by about 50%. At each site, amongst the three natural components considered, the strongly bound water makes the greatest contribution to the mean or median concentrations of PM ₁₀ , followed by NaCl, and SOC respectively. Strongly bound water was shown to have the biggest effect on the number of days on which the PM ₁₀ concentrations exceeded a value of 50 µg/m ³ ; however, removal of estimated NaCl and SOC components also had a noteworthy effect on reducing PM ₁₀ concentrations. Therefore, application of this proposed measure would make a very major difference to the likelihood of compliance or otherwise with the 24-h limit value for PM ₁₀ . |

| Period | April 28-May 23, 2003 |
| Location | Street canyon intersection in Central London, UK |
| Population | Users of an urban street canyon intersection |
| Age Groups | NR |
| Indoor Source | NR |
| Personal Method | PM _{2.5} measured using high-flow gravimetric personal samplers (PM _{2.5}) operating at a flow rate of 16 l/min carried in a backpack with sampling head positioned in personal breathing zone; Ultrafine particles measured using TSI P-TRAK Ultrafine Particle Counters in which ambient aerosol mixes with isopropyl alcohol. Alcohol condenses to form droplets that can be easily counted by a photodetector as they pass through a laser beam. |
| Personal Size | PM _{2.5} , Ultrafine particles (UFP, 0.02-1.0µm) |
| Microenvironment Size | PM _{2.5} , Ultrafine particles (UFP, 0.02-1.0µm) |
| Ambient Size | PM _{2.5} |
| Component(s) | NR |
| Primary Findings | Personal exposures to PM _{2.5} while walking were significantly lower than while riding in a car or taxi, likely a function of greater distance to roadside. No significant differences in PM _{2.5} were observed between exposures on the high traffic road compared with the backroad. Personal exposure levels were lowest during midday measurements for PM _{2.5} and highest in the early evening. Personal exposures to ultrafine particles were lowest while walking and highest while riding the bus. Exposures to ultrafine particles were also significantly higher on the high traffic road and during morning measurements. Exposure to ultrafine particles were highest in the morning, likely the result of peak traffic density in the morning. Exposure assessment also revealed that the background and curbside monitoring stations were not representative of the personal exposure of individuals to PM _{2.5} and CO at and around a street canyon intersection. |

|------------------------------|--|
| Study Design | Comprehensive exposure assessment. "The research was part of an intensive exposure assessment and health effects panel study of susceptible sub-populations in Seattle from; 1999 through 2002 (Liu et al., 2003, 073841)." |
| Period | 10-day monitoring session winter 2000-2001; 10-day monitoring session spring 2001 |
| Location | Seattle, WA |
| Population | Asmatic children |
| Age Groups | 6-13 yr |
| Personal Method | Harvard personal environmental monitors; Continuous PM monitors (nephelometers); Harvard Impactors; TEOM monitors; and exhaled breath measurements into an NO-inert Mylar balloon |
| Personal Size | PM _{2.5} |
| Microenvironment Size | PM _{2.5} |
| Ambient Size | PM _{2.5} |
| Component(s) | NR |
| Primary Findings | This study found a consistent relationship between daily eNO values in children with asthma and daily PM _{2.5} measured at fixed sites and on subjects. As hypothesized, the authors found that the use of ICS therapy modified the association between eNO and PM _{2.5} . Including ambient NO values for the hour of the home visit from a central site in the model and discarding high NO days (>100 ppb) attenuated the magnitude but did not alter the association between PM _{2.5} and eNO in all analyses. Same-day outdoor, indoor, personal, and central PM _{2.5} levels were associated with eNO in either analysis. These data suggest ambient PM _{2.5} exposure in Seattle is associated with an increase in eNO in children with asthma. Because eNO is a marker of airway inflammation, and PM has been shown to cause inflammation in animal studies, this result is biologically plausible. This finding also agrees with previous asthma research in Seattle that showed associations between PM _{2.5} and lung function decrements in children with asthma. |

| | |
|------------------------|--|
| Study Design | Population based exposure assessment |
| Period | October 1996 to June 1998 |
| Location | Helsinki, Finland; Basel, Switzerland; Prague, Czech Republic; Athens, Greece |
| Population | Adult urban populations |
| Age Groups | 25-55 yr |
| Indoor Source | NR, Workplace and residential outdoor samples could not be collected for every participant. The number of non-ETS-exposed participants was particularly small in Prague (12) and Athens (29), and therefore, these results from these cities should be interpreted with caution. The population sampling and sample representativity issues are described in detail in Rotko et al. (2000, 012118), and, for the Basel sample, in Oglesby et al. (2000, 001832). |
| Personal Method | The 48 h PM _{2.5} exposure was measured by a personal exposure monitor (PEM). Two filter holders were provided for each participant. One 'workday filter' for work and commuting, about 2 8–10 h, and one "leisure time filter" for the remaining time. Microenvironmental PM _{2.5} monitors (MEMs) were placed at the participant's home outdoors and indoors and in their workplaces. The pumps were programmed to run at home outdoors and indoors during the expected leisure time hours and at workplace during |

| | |
|------------------------------|--|
| | expected working hours of each participant. The personal and microenvironmental PM _{2.5} sampling methods and QA/QC results are presented in detail in Koistinen et al. (1999, 010628). |
| Personal Size | PM _{2.5} |
| Microenvironment Size | PM _{2.5} |
| Ambient Size | PM _{2.5} ; PM ₁₀ |
| Component(s) | NR |
| Primary Findings | In Helsinki the concentration associations are high between the outdoor air concentrations of PM _{2.5} and PM ₁₀ measured simultaneously at different locations. The highest exposure correlations are observed between the personal exposures and the respective indoor air concentrations. Correlations between the personal exposures and outdoor/ambient air concentrations are considerably lower (all centers). Personal exposures during leisure time correlate better with outdoor/ambient concentrations than during the workday (Helsinki and Prague). Leisure time and workday exposures correlate poorly with each other (all centers). Removing ETS improved the correlations between personal (indoor) air and ambient (outdoor) air, but decreased the correlations between personal exposures and indoor air concentrations and also between the personal exposures during workday and leisure time. In spite of these generalizations, there are considerable differences between the cities. |

| Study Design | Panel study |
| Period | Baltimore 6/28/98-8/22/98 (summer), 2/1/99-3/16/99 (winter); Boston 6/13/99-7/23/99 (summer), 2/1/00-3/12/00 (winter) |
| Location | Baltimore, MD Boston, MA |
| Population | Healthy older adults, children, adults with COPD |
| Age Groups | Children 9-13 y/o; Seniors 65+ y/o; COPD Subjects NR |
| Indoor Source | No |
| Personal Method | Personal exposure samples of PM _{2.5} ; were collected using a specially designed multipollutant sampler (Demokritou et al. 2001). PM _{2.5} was collected using personal environmental monitors (PEMs) and 37-mm; Teflon filters (Teflo, Gelman Sciences, Ann Arbor MI). |
| Personal Size | PM _{2.5} |
| Microenvironment Size | NR |
| Ambient Size | PM _{2.5} |
| Component(s) | Elemental Carbon (EC); SO ₄ ²⁻ |
| Primary Findings | Ambient PM _{2.5} and SO ₄ are strong predictors of respective personal exposures. Ambient SO ₄ is a strong predictor of personal exposure to PM _{2.5} . Because PM _{2.5} has substantial indoor sources and SO ₄ does not, the investigators; concluded that personal exposure to SO ₄ accurately reflects exposure to ambient PM _{2.5} and therefore the ambient component of personal exposure to PM _{2.5} as well. |

Kulkarni and Patil (2003, [156664](#))

| | |
|------------------------------|---|
| Study Design | Personal exposure assessment of toxic metals |
| Period | NR |
| Location | Mumbai, India; Two localities or sites, namely, Marol and Sakinaka, denoted as Sites 1 and 2 respectively |
| Population | Outdoor workers- low-income group population working and residing in industrial areas |
| Age Groups | NR |
| Indoor Source | low grade cooking fuel and inadequate ventilation |
| Personal Method | A personal sampler (Cassela/ SKC make), which consists of a diaphragm pump and operates on rechargeable batteries, was used along with a cyclone to measure personal exposure to respirable PM (RPM). The device was fitted to the waist belt of the respondent and connected by a flexible tube to the cyclone, which can be clipped to the shirt collar. The inlet of the cyclone was kept near the breathing level of the respondent. After working hours, the personal sampler was worn by the respondent in his/ her residence. Before sleeping, the sampler was removed from the waist and kept in the "on" condition as close to the breathing level as possible.; The RPM in ambient air was measured simultaneously by using high volume sampler (HVS) with a cyclone attachment for removal of particles with size greater than 10 µm. |
| Personal Size | PM5 |
| Microenvironment Size | NR |
| Ambient Size | PM5 |
| Component(s) | Lead; Nickel; Cadmium; Copper; Chromium; Potassium; Iron; Manganese |
| Primary Findings | All listed metals were detected in the ambient air where as only Lead, Cadmium, Manganese, and Potassium were detected in personal exposures. Mean daily exposure to lead exceeds the Indian NAAQS by a factor of 4.2. However, ambient concentration of lead conforms to this standard. There is a rising trend in the personal exposures and ambient levels of cadmium. However, they are low and do not pose any major health risk as yet. Personal exposures to toxic metals exceed the corresponding ambient levels by a large factor ranging from 6.1 to 13.2. Thus, ambient concentrations may underestimate health risk due to personal exposure of toxic metals. Outdoor exposure to toxic metals is greater than the indoor (ratios ranging from 2.3 to 1.1) except for potassium (ratio 0.77). However, there is no significant correlation between these two. |

| Study Design | Personal exposure study |
| Period | December 1998-February 2000 |
| Location | Oxford, UK |
| Population | Adults |
| Age Groups | 25-55 yr (avg = 41) |
| Indoor Source | Cooking, active smoking, passive smoking heating by gas heater |
| Personal Method | Personal exposure monitors (PEM) were carried by the participant for 48-h personal sampling, and microenvironmental monitors (MEM) were placed inside the participant's home (residential indoor), outside the home (residential outdoor) and in the participant's workplace (workplace indoor).; The PM _{2.5} samplers used were GK2.05 cyclones (KTL) with 2µm pore Gelman Teflo filters, and WINS PM _{2.5} impactors for personal exposure and residential outdoor samples, respectively. VOC sampling was accomplished with Perkin Elmer Tenax-TA tubes, CO Enhanced Measurer T15s were used for CO samples, and NO ₂ passive sampling badges were used to sample NO ₂ . No residential outdoor CO or NO ₂ samples were taken. |
| Personal Size | PM _{2.5} |
| Microenvironment Size | PM _{2.5} |
| Ambient Size | PM _{2.5} |
| Component(s) | Ag Cr Mn Si; Al Cu Na Sm; As Fe Ni Sn; Ba Ga P Sr; Br Ge Pb Ti; Ca Hg Rb Tl; Cd I S Tm; Cl K Sb V; Co Mg Se Zn; Zr |
| Primary Findings | Both the indoor and outdoor environments have sources that elevated the indoor concentrations in a different extent, in turn led to higher personal exposures to various pollutants.; Geometric mean (GM) of personal and home indoor levels of PM _{2.5} , 14 elements, total VOC (TVOC) and 8 individual compounds were over 20% higher than their GM outdoor levels. Those of NO ₂ , 5 aromatic VOCs, and 5 other elements were close to their GM outdoor levels. For PM _{2.5} and TVOC, personal exposures and residential indoor levels (in GM) were about 2 times higher among the tobacco-smoke exposed group compared to the non-smoke exposed group, suggesting that smoking is an important determinant of these exposures. Determinants for CO were visualized by real-time monitoring and that the peak levels of personal exposure to CO were associated with smoking, cooking and transportation activities. Moderate to good correlations were only found between the personal exposures and residential indoor levels for both PM _{2.5} (r = 0.60; p < 0.001) and NO ₂ (r = 0.47; p = 0.003). |

| Study Design | Longitudinal exposure assessment |
| Period | January 4-14, 2001 |
| Location | Taipei, Taiwan; (highway toll station) |
| Population | Highway toll station workers |
| Age Groups | 19.3-43.6 yr; mean = 25.7 ± 5.71 |
| Indoor Source | Indirect exposure assessment was based on information on (a) lane-specific traffic density (available for all lanes throughout the study period), (b) estimated relationships between lane- and shift-specific traffic density and the average PM _{2.5} concentrations, and (c) information on time periods spent by individuals in different working environments. |

| | |
|------------------------------|--|
| Personal Method | Direct exposure assessments were conducted by installing battery-operated personal PM _{2.5} monitors (University Research Glassware Corp.) in the booth near the breathing zone of the workers. |
| Personal Size | PM _{2.5} |
| Microenvironment Size | NR |
| Ambient Size | NR |
| Component(s) | NR |
| Primary Findings | Toll workers on Taipei highways are exposed high concentrations of PM _{2.5} . Mean PM _{2.5} concentration per vehicle in the truck and bus lanes was 6.4 and 3.7 times higher, respectively, than that of ticket- or car-payment car lanes. There was a statistically significant correlation between traffic density and PM _{2.5} concentrations in car lanes with ticket payments and truck and bus lanes. Wind speed and humidity had a significant inverse association with PM _{2.5} concentration in car lanes with ticket and cash payments. Bus and truck lane was the strongest determinant of log (PM _{2.5}). The results of this study show that personal exposure to PM _{2.5} can be reliably estimated using indirect traffic approaches. |

| Study Design | Cross-sectional |
| Period | NR, but prior to 2006 |
| Location | Charleston, Ottawa, Clarksville, Ohio |
| Population | Farmers |
| Age Groups | NR, but prior to 2006 |
| Indoor Source | Hogs, poultry, cattle, feed, bedding |
| Personal Method | The dust & microorganisms passed thru an optical particle counter and a filter sampler to collect airborne microorganisms. |
| Personal Size | 0.7-1 µm; 1-2 µm; 2-3 µm; 3-5 µm; 5-10 µm; Total dust |
| Microenvironment Size | NR |
| Ambient Size | NR |
| Component(s) | Fungal spores and bacteria |
| Primary Findings | The highest contribution of large particles (3-10 µm) in total particles was found during grain harvesting. In animal confinements the particles were dominated by smaller particles <3 µm. A high proportion of the particles between 2 and 10 µm were fungal spores. |

| | |
|---------------------|---|
| Study Design | Personal exposure study to investigate the occurrence of systematic differences in the PE exposure to motor exhaust and to study if these are influenced by the choice of exposure indicator gaseous or particulate |
|---------------------|---|

| | |
|------------------------------|--|
| Period | Sep 1997 to Oct 1999 |
| Location | Stockholm, Sweden |
| Population | Taxi, bus, and lorry drivers |
| Age Groups | NR |
| Indoor Source | NR |
| Personal Method | PM was measured with a logging instrument Data-RAM, using nephelometric monitoring (Data-RAM measures PM 0.1 to 10 µm) |
| Personal Size | PM ₁₀ |
| Microenvironment Size | NR |
| Ambient Size | PM ₁₀ |
| Component(s) | NR |
| Component(s) | NO ₂ |
| Primary Findings | 1) Lorry drivers experienced the highest exposure and taxi drivers the lowest with bus drivers in an intermediate position, regardless of whether NO ₂ or particles were used as exposure indicator; 2) The levels of both NO ₂ and particles were higher for bus drivers in the city than for them driving in the suburbs; 3) Using diesel or petrol as a fuel for taxis had no influence on the exposure for the drivers, indicating that the taxi drivers' exposure mainly depends on exhaust from surrounding traffic. |

|------------------------------|---|
| Study Design | 7 groups of occupations defined by common or high exposure to DE |
| Period | Oct 2002-June 2004 |
| Location | Stockholm, Sweden |
| Population | Persons exposed to DE |
| Indoor Source | Vehicle exhaust |
| Personal Method | Pump units and gravimetric for PM ₁ & PM _{2.5} and real-time monitoring of elemental carbon and total carbon. Diffusive samplers for NO ₂ as an indicator of the gas phase of exhaust. |
| Personal Size | PM ₁ , PM _{2.5} , and DataRAM (PM _{0.1-10}) |
| Microenvironment Size | NR |
| Ambient Size | NR |
| Component(s) | elemental carbon (EC), total carbon (TC) |
| Primary Findings | Tunnel construction workers had the highest levels of exposure for all indicators, followed by diesel-exposed garage workers. The other 5 groups were significantly lower with no difference between the groups. |

Li et al. (2003, [047845](#))

| | |
|------------------------------|--|
| Study Design | Concurrent 10-min avg indoor and outdoor concentrations of PM ₁₀ and PM _{2.5} were recorded for 2 days each in 10 homes with swamp coolers |
| Period | Summer 2001 |
| Location | El Paso, Texas |
| Population | Cooking, cleaning, walking |
| Age Groups | NR |
| Indoor Source | NR |
| Personal Method | PM _{2.5} and PM ₁₀ ; indoor and outdoor; tapered element oscillating microbalance (TEOM) instruments. 2 days were monitored for PM _{2.5} , and 2 for PM ₁₀ . |
| Personal Size | NR |
| Microenvironment Size | NR |
| Primary Findings | Evaporative coolers were found to act as PM filters, creating indoor concentrations approximately 40% of outdoor PM ₁₀ and 35% of outdoor PM _{2.5} , regardless of cooler type. |

Liao et al. (2006, [188451](#))

| | |
|------------------------------|---|
| Study Design | Case study |
| Period | January 18-27, 2003 |
| Location | Changhwa, Central Taiwan |
| Population | Traditional Taiwanese residences |
| Indoor Source | Chinese style cooking, incense burning, cleaning, and people's moving |
| Personal Method | A portable laser dust monitor (DM1100) was used to analyze the indoor and outdoor PM characteristics. The DM1100 was placed in a single indoor location, 1.5 m above the floor, adjacent to areas of the kitchen, altar, and living room where the housing activities occurred. |
| Personal Size | NR |
| Microenvironment Size | PM _{0.5-5} |
| Ambient Size | PM _{0.5-5} |
| Component(s) | NR |
| Primary Findings | Results indicate that only 2.6-8% of indoor particles are from outdoor sources. Both indoor and outdoor PM concentrations increase with PM size intervals, as do the deposition rates from cooking events; Authors suggest that "results revealed that cooking and incense burning events were major contributors to indoor concentrations for the particle sizes 1-5 µm. Results demonstrated the importance of knowing the time-activity data and the real-time indoor and outdoor particle size distribution information for |

understanding exposure to particles of indoor sources. More importantly, this research illustrates that an exposure assessment based on PM_{0.5-5} measured indoors can provide valuable information on the fate of indoor particles and hazard to human health.”

Liu et al. (2003, [073841](#))

| | |
|------------------------------|--|
| Study Design | Part of a larger exposure assessment and health effect panel study |
| Period | Winter 2000-2001 and spring 2001 |
| Location | Seattle, WA |
| Population | Children with asthma |
| Age Groups | 6-13 yr |
| Indoor Source | NR |
| Personal Method | Personal PM _{2.5} measurements were collected from each subject using the Harvard personal environmental monitors. |
| Personal Size | PM _{2.5} |
| Microenvironment Size | PM _{2.5} |
| Ambient Size | PM _{2.5} |
| Component(s) | NR |
| Primary Findings | The ambient-generated component of PM _{2.5} exposure was consistently associated with increases in eNO and the indoor-generated component was less strongly associated with eNO. As a result, the eNO results support the hypothesis that PM _{2.5} of outdoor origin could be more potent per unit mass than particles of indoor origin. However, the lung function data indicate that PM _{2.5} of indoor origin might be more potent per unit mass in resulting in decrements of lung functions, although the results across functional tests were not consistent. The authors tentatively concluded that partitioning personal exposure into indoor- versus outdoor-generated particles is useful in understanding the health effects of sources of personal PM _{2.5} and that the effects of indoor- versus outdoor-generated particles differ for different health points. |

| Study Design | Exposure assessment, validation set within a prospective occupational cohort (boiler workers) |
| Period | NR (healthy working adults) |
| Population | |
| Personal Method | Yes, A personal environmental monitor (PEM, Model 200, MSP Co, Shoreview, MN) with a pump at 4L/min |
| Personal Size | PM ₁₀ |
| Microenvironment Size | PM ₁₀ |
| Ambient Size | NR |
| Component(s) | Metals Vanadium (V), Nickel (Ni), Iron (Fe), Chromium (Cr), Cadmium (Cd), lead (Pb), Manganese (Mn) |
| Primary Findings | The validation demonstrated good approximations of actual exposures with differences less than 5% for PM. |

Liu et al. (2003, [073841](#))

| | |
|------------------------------|--|
| Study Design | Comprehensive exposure assessment |
| Period | 1999-2001 |
| Location | Seattle, WA |
| Population | High-risk sub populations |
| Age Groups | Children 6-13 yr; elderly 65-90 yr (one person was below 65 but not specified) |
| Personal Method | Personal PM _{2.5} exposures were determined using the Harvard Personal Environmental Monitor for PM _{2.5} (HPEM _{2.5}). Each subject carried an HPEM _{2.5} in the breathing zone for 24 h, except while sleeping, showering, or using the restroom. The monitor was attached to the shoulder strap of either a backpack or a fanny pack that contained the air pump. When the monitor was not worn, it was placed at an elevation of 3–5 feet (e.g., on a table) close to the subjects.; The indoor and outdoor PM concentrations were measured with single-stage inertial Harvard Impactors (HI) and 37 mm Teflon filters for PM ₁₀ and PM _{2.5} . One HI _{2.5} -HI ₁₀ pair was located inside each home in the main activity room and connected to a Medo pump (model vp0935a). Concurrently, one HI _{2.5} -HI ₁₀ pair was located outside each home and connected to a Gast pump (model DOA-V191-AA). All HI sampling periods were for 24 h at a flow rate of 10 L/min. HI _{2.5} , HI ₁₀ , and HPEM _{2.5} were also co-located with the federal reference method monitor for PM _{2.5} (FRM _{2.5}) at the central Beacon Hill site, which is located in a semiresidential area (elevation, 300 feet) and is maintained by the Washington State Department of Ecology. |
| Personal Size | PM _{2.5} ; PM ₁₀ |
| Microenvironment Size | PM _{2.5} ; PM ₁₀ |
| Ambient Size | PM _{2.5} ; PM ₁₀ |
| Primary Findings | The average personal exposures to PM _{2.5} were similar to the average outdoor PM _{2.5} concentrations but significantly higher than the average indoor concentrations. Indoor and outdoor PM _{2.5} , PM ₁₀ , and the ratio of PM _{2.5} to PM ₁₀ were significantly higher during the heating season. The increase in outdoor PM ₁₀ in winter was primarily due to an increase in the PM _{2.5} fraction. A similar seasonal variation was found for personal PM _{2.5} . The children in the study experienced the highest indoor PM _{2.5} and PM ₁₀ concentrations. Personal PM _{2.5} exposures varied by study group, with elderly healthy and CHD subjects having the lowest exposures and asthmatic children having the highest exposures. Within study groups, the PM _{2.5} exposure varied depending on residence because of different particle infiltration efficiencies; PM _{2.5} exposures among the COPD and CHD subjects can be predicted with relatively good power with a microenvironmental model composed of three microenvironments. The prediction power is the lowest for the asthmatic children. |

| | |
|------------------------------|---|
| Study Design | Comprehensive study of key contaminants |
| Period | Ottawa, Ontario, Canada |
| Location | NR |
| Population | NR |
| Age Groups | NR |
| Personal Method | PM _{2.5} and PM ₁₀ filter samples were collected in the living room of each home for 7 days, using SKC sampler model 200 PEM on tared teflon filters. Concurrent PM _{2.5} samples were collected on 47-mm Teflo 2-µm filters with MiniVol air samplers mounted on a tripod ~2 m in front of the house. Particulate samples for analysis of airborne endotoxin, ergosterol, and β1, 3-D-glucan were collected on a three-piece cartridge equipped with an endotoxin-free polycarbonate filter in the living room and bedrooms of each home. In the living room, samplers were located at a height between 1.22 m and 1.83 m from the floor and no closer than 0.5 m to surfaces. In bedrooms, the samples were collected as close to the beds as feasible. BC concentrations were continuously recorded for 7 days with a Magee Scientific Aethalometer in the living room of each house. |
| Personal Size | NR |
| Microenvironment Size | PM _{2.5} ; PM ₁₀ |
| Ambient Size | NR |
| Component(s) | BC; Also assessed: Endotoxin; Ergosterol; Glucan; Dust samples Dust >300; Der p1; Der f1; Fel d1; |
| Primary Findings | Airborne concentrations of the contaminants measured generally were unremarkable, although the mass of settled dust per square meter was well above that associated with increased asthma and comfort symptoms clinical response, particularly in urban homes. When co-occurrence of inflammatory agents and dust mite allergen burdens in the houses was considered, three homes had higher relative amounts of the agents considered. Based on what is known about clinical interactions between, for example, endotoxin and dust mite allergens, a combined exposure possibly results in an increased relative risk of allergic disease. |

|------------------------------|--|
| Study Design | Indoor/outdoor exposure assessment related to domestic wood burning |
| Period | 10 February to 12 March 2003 |
| Location | Hagfors, Sweden |
| Population | Adult residents of Hagfors |
| Age Groups | NR |
| Indoor Source | NR |
| Personal Method | Identical sets of equipment were used for both personal exposure and indoor sampling a GK2.05 (KTL) cyclone connected to a BGI 400S Personal Sampling Pump with a flow rate of 4 l min ⁻¹ . Each person was equipped with an easily carried shoulder bag with the cyclone and pump attached to it. The cyclone was attached to the shoulder strap and placed near the breathing zone. The personal sampler was worn all day, and at night it was placed next to the stationary indoor sampler in the living room, owing to the noise of the pump.; Two different types of impactors were used for the outdoor sampling one Sierra Andersen series 240, dichotomous virtual impactor that separates particles into two size ranges, coarse and fine particles (PM _{10-2.5} and PM _{2.5} , respectively); and one EPA-WINS impactor (PQ100 EPA-WINS Basel PM _{2.5} Sampler) for collecting PM _{2.5} particles. The outdoor measurements were made at a single location on the roof of a single car garage, belonging to one of the subjects, in the middle of the study area. |
| Personal Size | PM _{2.5} |
| Microenvironment Size | PM _{10-2.5} ; PM _{2.5} |
| Ambient Size | PM _{10-2.5} ; PM _{2.5} |
| Component(s) | BS; S; Cl; K; Ca; Mn; Fe; Cu; Zn; Br; Rb; Pb |
| Primary Findings | Statistically significant contributions of wood burning to personal exposure and indoor concentrations have been shown for K, Ca, and Zn. Increases of 66–80% were found for these elements, which seem to be good wood-smoke markers. In addition, Cl, Mn, Cu, Rb, Pb, and BS were found to be possible wood-smoke markers, though not always to a statistically significant degree for personal exposure and indoor concentrations. For some of these elements subgroups of wood burners had clearly higher levels which could not be explained by the information available. Sulfur, one of the more typical elements mentioned as a wood-smoke marker, showed no relation to wood smoke in this study due to the large variations in outdoor concentrations from LDT air pollution. This was also the case for PM _{2.5} mass. Personal exposures and indoor levels correlated well among the subjects for all investigated species, and personal exposures were generally higher than indoor levels. The correlations between the outdoor and personal or ind |

| Study Design | Cross-sectional |
| Period | Autumn and spring in 2002 and 2003 |
| Location | Goteborg, Sweden, |
| Population | Persons living in urban settings |
| Age Groups | 20 subjects 20-50 yr randomly selected from the population and 10 from departmental colleagues. |
| Indoor Source | NR |
| Personal Method | The volunteer subjects had a small shoulder bag with one PM _{2.5} cyclone and a pump attached. Intake was in the breathing zone. Pump was carried during the day and placed next to the indoor cyclone during the night.; Ten subjects from their staff wore 2 sets of sampling equipment near the breathing zone. A GK2.05 cyclone for PM _{2.5} and a Triplex cyclone for PM ₁ in a small shoulder bag. |
| Personal Size | PM _{2.5} and PM ₁ |
| Microenvironment Size | NR |

Ambient Size NR
Component(s) S; Cl; K; Ca; Ti; V; Mn; Fe; Ni Cu; Zn Br Pb.
Primary Findings PM_{2.5} personal exposures were significantly higher than both outdoor and urban background for the elements Cl, K, Ca, Ti, Fe, and Cu.; Personal exposure was also higher than indoor levels of Cl, Ca, Ti, Fe, and Br, but lower than outdoor Pb. Residential outdoor levels were significantly higher than the corresponding indoor levels for Br and Pb, but lower for Ti and Cu. The residential levels were also significantly higher than the urban background for most elements.

Molnár et al. (2007, [156774](#))

Study Design Microenvironmental monitoring of PM and elements in 10 schools, 10 preschools, and 20 non-smoking homes.
Period 1 Dec 2003- 1 July 2004
Location Stockholm, Sweden
Population Children
Age Groups 6-11 yr (no pre-school children) but sampling was conducted at 10 preschools.
Indoor Source Smoking, gas stoves,
Personal Method NR
Personal Size NR
Microenvironment Size NR
Ambient Size NR
Component(s) S; K; Ca; Ti; V; Cr; Mn; Fe; Ni; Cu; Zn; Br; Pb
Primary Findings Significantly lower indoor concentrations of S, Ni, Br and Pb, elements from long-range transported air masses, were found in all locations. Only Ti was significantly higher indoors in all locations, probably because of TiO₂ in paint pigment. Similar differences were found during both seasons for homes and schools. At preschools the infiltration of the long-range transported elements S, Br and Pb was lower in winter than in spring, and also the crustal elements Ti, Mn and Fe had higher indoor concentrations during spring. There were spatial differences outdoors, with significantly lower concentrations of elements of crustal and traffic origin in the background area community.

Monkkonen et al. (2005, [156775](#))

Study Design Human exposure assessment in homes in India
Period Nagpur Mar to Oct 2002; Mysore Aug to Dec 2002
Location Nagpur and Mysore, India
Population Residential homes in India
Age Groups NR
Indoor Source Yes; cooking w/ kero. and LPG; Toaster; Burning incense; Infiltration of outdoor air; Burning coconut husks
Personal Method TSI Condensation Particle Counter Model 3007 (CPC counts all particles >10 nm); TSI Model 8520 Dust Trak; PM_{2.5} Environmental Monitor with Whatman PTFE membrane filters and gravimetric analysis
Personal Size PM_{2.5} for mass (µg/m³); Total PM for counts (particles/cm³)
Microenvironment Size PM_{2.5} for mass (µg/m³); Total PM for counts (particles/cm³)
Ambient Size Total PM for counts (particles/cm³)
Component(s) NR
Primary Findings The maximum concentrations observed in most cases were due to indoor combustion sources. Besides cooking stoves that use LPG or kerosene as the main fuel, high indoor concentrations can be explained by poor ventilation systems.

Mwaiselage et al. (2006, [156789](#))

Study Design Cross-sectional; personal monitoring. To determine the effects of cement exposure on acute respiratory health.
Period June-August 2001
Location Dar es Salaam, Tanzania
Population Cement factory workers
Age Groups NR
Indoor Source Cement production
Personal Method Cellulose Acetate Filter, Sidekick pump
Personal Size Respirable dust, total dust
Microenvironment Size NR
Ambient Size NR
Component(s) Ca, Al, Fe, K
Primary Findings Results of Cox Regression analysis showed that prevalence ratios for cough, short breathness and stuffy nose for high exposed workers in the production department compared to low exposed workers in the low exposed workers working in the maintenance department and the administration building are 6.7, 4.5 and 1.9 respectively. Cross shift decrease in PEF was more in the higher among high exposed workers (7.6%) than low exposed workers (2.7%). The observed acute acute respiratory health effects are most likely related to exposure of workers to high concentrations of irritant cement dust.

| | |
|------------------------------|---|
| Study Design | RIOPA Study-PAH partitioning indoor and outdoor. To evaluate the hypothesis that outdoor air pollution contributed strongly to indoor air pollution. |
| Period | July 1999-June 2000 |
| Location | Los Angeles, CA, Houston, TX, Elizabeth, NJ |
| Population | Houses |
| Age Groups | NR |
| Indoor Source | NR |
| Personal Method | Modified MSP Samplers, 37 mm quartz filter |
| Personal Size | NR |
| Microenvironment Size | Filter, PM _{2.5} |
| Ambient Size | Filter, PM _{2.5} |
| Component(s) | Organic Carbon (OC), Elemental Carbon (EC) |
| Primary Findings | Multiple linear regression (MLR) log PAH particulate partition coefficient (kp) vs log vapor pressure coefficient (std) 0.888 (0.009) fraction of elemental carbon in PM coefficient (std) 3.686 (0.238) fraction of elemental carbon in PM coefficient (std) 0.469 (0.055) temperature coefficient (std) -0.0456 (0.002) intercept (std) 8.398 (0.604) R ² = 0.845. Both EC and OC carbon are important predictors of gas/particle partitioning of PAHs, with EC being a better predictor. Because EC is highly correlated with (and is a good tracer of) primary combustion-generated OC, this result suggests that PAHs more readily sorb on combustion-generated aerosol containing EC. Enrichment of the indoor aerosol in non-combustion OC suggests that sorption of PAHs is more important in the indoor air compared to the outdoor air. The MLR developed in this work will improve prediction of gas/particle partitioning of PAHs in indoor and outdoor air. |

|------------------------------|--|
| Personal Size | PM _{2.5} |
| Microenvironment Size | NR |
| Ambient Size | PM _{2.5} |
| Component(s) | SO ₄ ; ABS (light absorbing carbon) |
| Primary Findings | In Prince George, a combination of topography, meteorological conditions and location of ambient sources resulted in episodic levels of fine PM during the short study period in the winter of 2001. Thermal inversions were moderately associated with both high ambient levels and personal exposures and were likely responsible for the spatial variation and, in combination with wind, the temporal variation in ambient concentrations throughout the city. The clear link between thermal inversions and both high ambient levels and measured personal exposures during PM _{2.5} episodes support management strategies to reduce ambient sources during periods of limited dispersion in an effort to reduce exposure levels. Despite the significant spatial variation found in ambient levels throughout the city for all three measures, there was a high correlation between the outdoor sites suggesting that a single monitor would represent temporal trends. Similar to the findings in other studies, both sulfate and light |

| | |
|------------------------------|---|
| Study Design | time-series epidemiologic study |
| Period | Site A (Group 1 [G1]); -Phase 1 July 6 to August 20, 2005; -Phase 2 October 19 to December 10, 2005; Site B Group 2 [G2]; -Phase 1 August 24 to October 15, 2005; -Phase 2 January 4 to February 18, 2006 |
| Location | Los Angeles, California (Two Retirement homes) |
| Population | Elderly residents of Los Angeles, California retirement homes |
| Age Groups | NR |
| Indoor Source | No |
| Personal Method | Two identical sampling stations were installed at each location, one indoors and one outdoors. The indoor sampling station at site A was located in the recreational area of the first community's main building, adjacent to a construction site where work was ongoing. The indoor sampling area at site B was situated in the dining room of the second community's main building. At both sites, the outdoor station, set up inside a movable trailer, was positioned within 300m from the indoor station. Two 11-attenuation mass monitors (BAMS) (Model 1020) were used at each indoor and outdoor sampling station to measure hourly PM _{2.5} mass concentrations. Continuous NO, NO ₂ , and CO measurements were taken indoors and outdoors using Thermo Environmental NOX analyzers (Model 42), and Dasibi CO Analyzers (Model 3008) respectively. O ₃ concentrations were also monitored at each sampling station by using API Ozone Analyzers (Model 400A). At both indoor and outdoor sampling areas, a water-based condensation particle counter (CPC model 3785), and a semicontinuous OC-EC analyzer (Model 3F) were operated side by side. A modified National Institute for Occupational Safety and Health (NIOSH) analysis protocol was used here to evolve particulate OC and EC. |
| Personal Size | NR |
| Microenvironment Size | PM _{2.5} |
| Ambient Size | PM _{2.5} , PN |
| Component(s) | OC; EC; OC1; OC2-4 |
| Primary Findings | Measured indoor and outdoor concentrations of PM _{2.5} , OC, EC, PN, O ₃ , CO, and NOX were generally comparable, although at G2, a substantial peak in indoor OC, PN, and PM _{2.5} (probably from cooking) was typically observed between 6:00 and 9:00 am. The study average percentage contribution of outdoor SOA to outdoor particulate OC was 40% and varied between 40% and 45% in the summer (during G1P1) and 32% and 40% in the winter (during G2P2). The low AERs (0.25-0.33 h ⁻¹) calculated for G1 and G2 are consistent with the structural characteristics of the sampling sites, the low number of open windows and doors, and the presence of central air conditioners. <i>F_{int}</i> estimates were highest for EC and also for OC. Lower <i>F_{int}</i> values were obtained for PM _{2.5} and PN, |

because these compounds are composed of both volatile and nonvolatile inorganic and organic compounds. Based on a single compartment mass balance model, it was found that 13-17% (G2P2) to 16-26% (G1P1) of measured indoor OC was emitted or formed indoors. Although the G2 indoor site was characterized by higher indoor morning OC peaks because of cooking, the overall contribution of indoor sources to measured indoor OC was higher at the G1 site. The modeling results also showed that the measured indoor PM_{2.5} emitted or formed indoors was highly variable (from 6-21% at G1P1 to 45-51% at G1P2). The average percentage contribution of indoor SOA of outdoor origin to measured indoor OC varied from ~35% (at site 1) to ~45% (at site 2). Also, outdoor-generated primary OC composed, on average, 36-44% of measured indoor OC during G2P1 and G1P1 respectively.

Study Design 2 types of samplers collected aerosols in an urban area. 23 samples were collected with each device separately for day and night.
Period Spring 2002
Location Budapest, Hungary
Population urban dwellers
Age Groups NR
Indoor Source NR
Personal Method NR
Personal Size NR
Microenvironment Size NR
Ambient Size See direct quote in the note below
Component(s) Al; Si; Ca; Ti; Fe; Cl; Zn; Na; Mn; Ni; Cu; Pb; K; S; Br
Primary Findings The variation in the overall size distributions and RMCs for the various elements indicated the existence of multiple sources, including vehicular (both combustion and frictional) and industrial emissions, resuspension of road and soil dust, and long-range transport of air masses. The significant coarse mode for some typical anthropogenic elements (Cu and Zn) and the observed coarse mode concentration differences between daytime periods and nights (e.g., for Ca) point to the importance of frictional sources and road dust resuspension in cities, which are both primarily related to road traffic.

Study Design examination of aerosol air quality and its temporal variation in the Budapest metro
Period April 20 and 21, 2006
Location Budapest, Hungary
Population underground metro commuters
Age Groups NR
Indoor Source No. Air monitoring equipment consisted of a tapered element oscillating microbalance (TEOM), a wind monitor (Campbell), and a laboratory-made Gent-type stacked filter unit (SFU) aerosol sampler. OM was equipped with a PM₁₀ inlet facing upwards and was operated with the filter heated to 40 °C to prevent moistening. The sampling station was ventilated without filtration by drawing air from the opposite platform to the roof level of a 12-story building next to the station.
Personal Method No personal monitoring. In situ aerosol measurement and sample collection at the metro station.
Personal Size PM_{10-2.0} and PM_{2.0}
Microenvironment Size NA
Ambient Size NR
Component(s) 30 elements (Na, Mg, Al, Si, P, S, Cl, K, Ca, Ti, V, Cr, Mn, Fe, Ni, Cu, Zn, Ga, Ge, As, Se, Br, Rb, Sr, Y, Zr, Nb, Mo, Ba, and Pb)
Primary Findings The concentrations observed in the Astoria underground station were clearly lower (by several orders of magnitude) than the corresponding workplace limits.

Sanderson and Farant (2004, [156942](#))

Study Design Indoor and outdoor air monitoring of PAH. Investigate the relationship between indoor and outdoor PAH.
Period NR
Location Canada
Population Residential homes in neighborhoods around aluminum smelting plant
Age Groups NR
Indoor Source NR
Personal Method Indoor quartz filter, XAD-2 Resin Outdoor glass fiber filter
Personal Size NR
Microenvironment Size NR
Ambient Size NR
Component(s) 4-6 ring PAHs on indoor particle
Primary Findings Indoor concentration of 4-6-ring PAH linked to outdoor sources in residences without any major indoor source, but with industrial facility as the main outdoor source. Study suggests that simultaneous measurements of indoor and outdoor concentrations of PAH >4 rings predominantly associated with fine PM could provide useful estimates of particle infiltration efficiency.

| Population | 13-19 yr |
| Age Groups | No |
| Indoor Source | Customized backpack |
| Personal Method | NR |
| Personal Size | NR |
| Microenvironment Size | NR |
| Ambient Size | NR |
| Primary Finding(s) | Most VOCs has median upper-bound lifetime cancer risks that exceeded the USEPA benchmark of 1×10^{-6} and were generally greater than the EPA modeled estimates, more so for compounds with predominant indoor sources. Chromium, nickel, and arsenic had median personal cancer risks above the benchmark with exposures largely from outdoors and other microenvironments. The EPA model overestimate risks for beryllium and chromium and underestimate risks for nickel and arsenic. |

| Study Design | Field Study |
| Period | Pilot Study; March 15-18, 1999, and March 22-25, 1999 (coal mine); April 12-14, 1999 (oil shale mine); Main Study; June 5-22, 2000 |
| Location | Pilot Study; Ostrava, Czech Republic (black coal mine); Kohtla-Järve, Estonia (oil shale mine); Main Study; Kohtla-Järve, Estonia (oil shale mine) |
| Population | Coal miners with high exposures to Diesel-powered machinery |
| Age Groups | NR |
| Indoor Source | NR |
| Personal Method | Personal sampling was accomplished by each individual worker carrying personal air sampling equipment (GSA 200 or Gillian) during two shifts in the same work week (1 shift for the main study). The air sampling pumps operated in the breathing zones of the individual workers and operated at an electronically controlled flow rate of 2.0l/min.; Inhalable dust samples were collected using a sampler head developed by the Institute für Gefahrstoff Forschung der Bergbau Berufsgenossenschaft (IGF). Respirable dust was collected using an elutriator pre-separator type MPGII (IGF). Particles were collected on polystyrene membrane filters with a Teflon coating. All samples were taken at a height of ~1.5 m above the floor. |
| Personal Size | NR |
| Microenvironment Size | NR |
| Ambient Size | NR |
| Component(s) | 1-nitropyrene (1-NP) |
| Primary Findings | This study confirms that 1-NP in black coal and oil shale mines is mostly associated with respirable particles and that mining operations involving diesel-powered engines exposures to DEP may be 3- to 10-fold higher for underground miners than workers on the surface. Furthermore, measurements of particle-associated 1-NP is a more sensitive and discriminating indicator of exposure to DEP than inhalable or respirable particles because of the relatively high concentrations of mine dust in mining operations.; Respirable dust concentration were 2- to 3-fold higher in the breathing zone than at fixed sampling locations while 1-NP concentrations were found to be 2.5-fold and 10-fold higher in the coal mine and oil shale mine respectively. This is thought to be due to location of fixed sampling points as well as wind and humidity levels within the mines themselves. For these reasons and others, personal air sampling is preferred over air sampling at fixed sites. |

| Study Design | Respirable particulates inside and outside of a building were collected and compared |
| Period | 24-h sampling from 12:45 pm Mondays to Fridays between 9/19/00 to 5/01/01 |
| Location | Wolverhampton city center, University of Wolverhampton, UK |
| Population | Building near traffic dominated by heavy-duty diesel vehicles |
| Indoor Source | Outdoor (primary); Mn,Al, NO ₃ , Cl ⁻ (wind-blown dust); Cu and Zn-(traffic emissions) |
| Personal Method | Active sampling using Casella sampler (filter)- |
| Personal Size | Respirable PM (inside and outside) |
| Microenvironment Size | Respirable PM (inside) |

Ambient Size Respirable PM (outside)
Component(s) Respirable PM, metals (Zn, Cu, Mn, Al), sulfate, nitrate, and chloride
Primary Findings The indoor particulate concentration was driven by ambient concentration; meteorological-induced changes in ambient PM were detected indoors.

Simons et al. (2007, [156982](#))

Study Design NR
Period Baltimore, Maryland; and surrounding counties
Location Children with asthma
Population Inner city-6-12 yr; Surrounding counties 6-17 yr
Age Groups Gas stoves, cats, dogs, smokers, mold/mildew carpet, outside PM, dryer vents
Indoor Source Indoor air was collected from the child's bedroom with 4 L/min MSP impactors over a 72-h Period.
Personal Method NR
Personal Size PM_{2.5}; PM₁₀
Microenvironment Size PM_{2.5}; PM₁₀
Ambient Size Allergens were also assessed Dust mite; Bla/g; Mus/m; Fel/d; Can/ f; Airborne Mus/m
Primary Finding(s) Compared with the homes of suburban children with asthma, the homes of inner city Baltimore children with asthma had higher levels of airborne pollutants (including PM, NO₂ and O₃ amongst others) and home characteristics that predispose to greater asthma morbidity. In the inner city homes, median and GM PM₁₀ levels were almost three times as high and the GM PM_{2.5} levels were more than three times higher than in the suburban homes. Median GM NO₂ and GM O₃ levels were found in similar ratios. It is important to note that PM₁₀ levels were found to be markedly higher in homes on arterial streets compared to those not on arterial streets. Although standards specific for home indoor air quality have not been established, the authors found that the inner city children were exposed to home pollutant levels in excess of the Environmental Protection Agency's National Ambient Air Quality standards.

Study Design Epidemiologic personal exposure study
Period Autumn- November 1999; Winter- January to February 2000; spring- April to May 2000; summer- August 2000
Location Central Copenhagen
Population University students
Age Groups 20-33 yr (median = 24 yr)
Indoor Source NR
Personal Method Particles were sampled using a KTL PM_{2.5} cyclone developed for the European EXPOLIS study (17), a International Gravity Bureau 400 pump (4l/min), and a battery pack. The equipment was placed in a backpack, which the subjects carried or placed nearby when they were indoor. Sampling was done on 37-mm Teflon filters.; Urban background concentrations of PM_{2.5} were measured on the rooftop of a building (20 meters above the ground) on the Copenhagen University campus.

| | |
|------------------------------|--|
| Personal Size | PM _{2.5} |
| Microenvironment Size | NR |
| Ambient Size | PM _{2.5} |
| Component(s) | BS |
| Primary Findings | Personal PM _{2.5} exposure was found to be a predictor of 8-oxodG in lymphocyte DNA. No other associations between exposure markers and biomarkers could be distinguished. ETS was not a predictor of any biomarker in the present study. The current study suggests that exposure to PM _{2.5} at modest levels can induce oxidative DNA damage and that the association to oxidative DNA damage was confined to the personal exposure, whereas the ambient background concentrations showed no significant association.; For most of the biomarkers and external exposure markers, significant differences between the seasons were found. Similarly, season was a significant predictor of SBs and PAH adducts, with average outdoor temperature as an additional significant predictor. |

Sørensen et al. (2005, [089428](#))

| | |
|------------------------------|---|
| Study Design | Repeated measures cohort study. |
| Period | Nov 1999-Aug 2000 |
| Location | Copenhagen, Denmark |
| Population | residents of downtown Copenhagen |
| Age Groups | 20-33 yr old, all non-smokers |
| Indoor Source | Used a questionnaire to get time exposed to environmental tobacco smoke, burning candles, frying food, open windows |
| Personal Method | wore a backpack, or placed nearby when indoors. |
| Personal Size | PM _{2.5} and BS |
| Microenvironment Size | Bedroom and front door; PM _{2.5} and BS |
| Ambient Size | Street monitoring station and roof of a campus building; PM _{2.5} and BS |
| Copollutant(s) | NO ₂ |
| Primary Findings | For NO ₂ there was a significant association between personal exposure and the bedroom, the front door and the background, whereas for PM _{2.5} and BS only the bedroom and the front door concentrations, and not the background, were significantly associated with personal exposure. The bedroom concentration was the strongest predictor of all three pollution measurements. The association between the bedroom and front door concentrations was significant for all three measurements, and the association between the front door and the background concentrations was significant for PM _{2.5} and NO ₂ , but not for BS, indicating greater spatial variation for BS than for PM _{2.5} and NO ₂ . For NO ₂ , the relationship between the personal exposure and the front door concentration was dependent upon the "season," with a stronger association in the warm season compared with the cold season, and for PM _{2.5} and BS the same tendency was seen. Time exposed to burning candles was a significant predictor of personal PM _{2.5} , BS and NO ₂ exposure, and time exposed to ETS only associated with personal PM _{2.5} exposure. These findings imply that the personal exposure to PM _{2.5} , BS and NO ₂ depends on many factors besides the outdoor levels, and that information on season or outdoor temperature and residence exposure, could improve the accuracy of the personal exposure estimation. Regression coefficients for personal exposure and front door PM _{2.5} in warm season was 0.67 *, and in the cold season, 0.28. Front door BS in warm season was 0.86 *, and in the cold season, 0.45.* Front door NO ₂ in warm season was 0.68 *, and cold season 0.32.* |

| Study Design | Exposure assessment of indoor environment |
| Period | April 5-June 26, 2000 |
| Location | Laboratory in Delhi, India |
| Population | Building occupants |
| Age Groups | NR |
| Indoor Source | Re-entrainment of existing dust on floor and other surfaces |
| Personal Method | No personal exposure assessment was conducted |
| Personal Size | NR |
| Microenvironment Size | Suspended PM (SPM) |
| Ambient Size | NR |

Component(s) metals Ca, Mg, Cu, Zn, Cd, Pb, Cr, Mn, Fe, Co, Ni
Primary Findings Gravimetric analysis and atomic absorption spectrometry results indicated that the suspended PM (SPM) and metal (lead) concentrations were higher than the National Ambient Air Quality Standards for Delhi, India and SPM standards for residential and sensitive areas. The maximum concentrations of SPM were observed to be due to penetration of outdoor particles originating from wind-blown crustal dust and vehicular pollution. Scanning electron microscopy analysis of particles showed dominance of crystalline silicon and spherical soot particles in samples.

| | |
|-------------------------|--|
| Ambient Size | NR |
| Component(s) | NR |
| Primary Findings | 1) In Mexico City, outdoor workers had greater DNA damage than indoor (median tail length 46.8 vs. 30.1 μm); 2) In Mexico City, outdoor workers had a greater proportion of cells with high DNA damage (tail length = 41 μm); 3) In Puebla, outdoor and indoor workers had similar damage; 4) DNA damage was correlated with $\text{PM}_{2.5}$ and ozone exposure; 5) High DNA damage in workers was associated with ozone, $\text{PM}_{2.5}$, and 1-ethyl-2-methyl benzene (VOC) exposure. |

Tovalin-Ahumada et al. (2007, [190165](#))

| | |
|------------------------------|--|
| Study Design | Point study |
| Period | April and May, 2002 |
| Location | Mexico City (Ne and SE) and Puebla, Mexico |
| Population | Indoor and outdoor workers in large urban areas |
| Age Groups | 18 years of age and older |
| Indoor Source | NR, The exposures described in this report were monitored as part of a larger study directed at evaluating the association between personal exposures to $\text{PM}_{2.5}$ and VOCs and genetic damage in outdoor and indoor workers reported elsewhere (Tovalin et al., 2006). |
| Personal Method | Personal exposures to $\text{PM}_{2.5}$ were monitored using 37mm Teflon filters (Model 225-9006, SKC Inc.), fitted to a single stage personal impactor (Model PEM-761-203A, SKC) and personal sampling pumps (Model PCXR4, SKC). Two $\text{PM}_{2.5}$ personal air samples (occupational and nonoccupational) were obtained during a 24-h period for each worker in Mexico City and for the indoor workers in Puebla. Only one $\text{PM}_{2.5}$ personal sample could be obtained during a 24-h period (an overall exposure) for the bus drivers in Puebla because of their work shift (from 4AM to 8 PM) with rotating start and end times. At the beginning of the work shift, each participant was asked to carry a backpack holding the pump; the impactor was attached to the backpack strap, in the breathing zone. At the end of the work shift, the impactor and pump were removed, and replaced with a new sampling setup that was worn by the worker until the beginning of the next day work shift. |
| Personal Size | $\text{PM}_{2.5}$ |
| Microenvironment Size | NR |
| Ambient Size | NR |
| Component(s) | Si; S; K; Ca; Cl(e); Ti; V; Cr; Mn; Fe; Co; Ni; Cu; Zn; Mo(e); Cd(e); Se; Br; Rb; Sr(e); As; Pb |
| Primary Findings | The results of this study suggest that outdoor workers in both Mexican cities experienced higher exposures to $\text{PM}_{2.5}$ than indoor workers, and that these exposures are well above either the 35 $\mu\text{g}/\text{m}^3$ US-EPA or the 65 $\mu\text{g}/\text{m}^3$ 24-h Mexican standards for $\text{PM}_{2.5}$. Both subgroups experienced higher occupational than non-occupational exposures. Mexico City outdoor workers had higher exposures to Soil, Fuels and Industrial emission-related elements than Puebla outdoor workers did. However, Mexico City outdoor workers had half the exposure to soil dust-related elements and fuel related elements than Puebla outdoor workers. However the S exposure was similar in all groups but high, product of the high vehicles density in the areas, responsible for 60% of the emission in Mexico City (Secretaria del Medio Ambiente, 2005). This study of Mexico City results correlates well with a previous $\text{PM}_{2.5}$ emissions inventory results, which determined that 81.14% of particles are released from mobile sources |

| Study Design | RIOPA Study 24-h integrated indoor, outdoor, and personal samples collected in 3 cites. |
| Period | Summer 1991-spring 2001 |
| Location | Elizabeth, NJ, Houston, TX, and Los Angeles County, CA |
| Population | 309 adults and 118 children (89-18) |
| Indoor Source | NR |
| Personal Method | PEM on the front strap of a harness near the breathing zone. The bag on the hip contained the pump, battery pack, and motion sensor |
| Personal Size | $\text{PM}_{2.5}$ |
| Microenvironment Size | $\text{PM}_{2.5}$, in the main living area (not kitchen) |
| Ambient Size | $\text{PM}_{2.5}$, in the front or back yard |
| Component(s) | 18 volatile organics, 17 carbonyl, $\text{PM}_{2.5}$ mass and >23 $\text{PM}_{2.5}$ species, organic carbon, elemental carbon, and PAHs |

Primary Findings The best estimate of the mean contribution of outdoor to indoor PM_{2.5} was 73% and the outdoor contribution to personal was 26%.

Urch et al. (2004, [055629](#))

Study Design The study was a crossover design in which each participant received a 2-h exposure to filtered air (FA) and CAP+O₃, assigned randomly and on separate occasions. Study objective is to examine the relationship between total and constituent PM_{2.5} mass concentrations and acute vascular response.

Period 2000-2001; not explicitly stated

Location Downtown Toronto, Canada

Population 24 young (35 ± 10 yr) healthy, nonasthmatic, nonsmoking people

Age Groups 35 ± 10years

Indoor Source NR

Personal Method During exposures a sample was collected immediately upstream to the participant on a 47 mm Gelman Teflon filter with a 2 µm pore size at an airflow of 15 L/min.

Personal Size PM_{2.5}

Microenvironment Size NR

Ambient Size PM_{2.5}

Component(s) Total carbon (elemental carbon, organic carbon), NO₃⁻, SO₄²⁻, NH₄⁺, K⁺, Cl⁻, Ca, Fe, Al, Mg, Zn, Mn, Pb, Cu, Ba, Se, Cr, Ni, V, Ar, Cd all have median, min, and max reported for ambient levels. NO₃⁻, SO₄²⁻, NH₄⁺ all have median, min, and max reported for directly measured personal exposure levels. Total carbon (elemental carbon, organic carbon), Ca, K⁺, Fe, Cl⁻, Al, Mg, Zn, Pb, Mn, Cu, Ba, Se, Cr, Ni, V, Ar, Cd all have median, min, and max reported for estimated personal exposure

Primary Findings A significant negative association between both the organic and elemental carbon concentrations and the difference in the post-exposure change in the BAD between CAP+O₃ and FA exposure days.

Vallejo et al. (2006, [157081](#))

Study Design 4/2002-8/2002

Period Mexico City, Mexico

Location Health young, non-smoking adults

Population Mean age 27 yr

Age Groups No

Personal Method pDR nephelometric method (personal DataRam, pDR1200)

Personal Size PM_{2.5}

Microenvironment Size NR

Ambient Size NR

Component(s) NR

Primary Findings Mean personal PM_{2.5} level was 74 mg/m³

Vallejo et al. (2006, [157081](#))

Study Design Pilot Study

Period April-August 2002

Location Mexico City, Mexico

Population Healthy residents of Mexico City

Age Groups 21-40 yr

Indoor Source NR

Personal Method The participant carried a personal PM_{2.5} monitor (DataRAM 1200) during a single 13-h period starting at 9:00 a.m. Indoor situations included activities at home, at work, at school, or in public places such as theaters, stores, restaurants coffee shops, and subway transportation. Outdoor activities included walking, standing, or sitting in an open space, driving a car or using public transportation (bus or taxi).

Personal Size NR

Microenvironment Size PM_{2.5}

Ambient Size PM_{2.5}

Component(s) NR

Primary Findings The descriptive analysis showed that overall outdoor median concentration of PM_{2.5} was higher than the indoor one. In the indoor microenvironment, the highest concentrations occurred in the subway followed by the school, and the lowest was at home. The outdoor microenvironment with the highest concentrations was the public transportation (bus), while the automobile had the lowest. It was found that PM_{2.5} concentration levels had a circadian-like behavior probably related to an increase in the population daily activities during the morning hours, which decrease in the evening, especially at indoor microenvironments. The Center city area was found to have the highest concentrations of PM_{2.5}; Multivariate analysis corroborated that PM_{2.5} concentrations are mainly determined by geographical locations and hour of the day, but not by the type of microenvironment.

| | |
|------------------------|--|
| Study Design | Inner City Air Pollution (ICAP) study- Randomized controlled trial |
| Period | NR |
| Location | Bronx, NY; Manhattan, NY; Boston, MA; Chicago, IL; Dallas, TX; Seattle, WA; Tucson, AZ |
| Population | Asthmatic children and their residences |
| Age Groups | 5-11 yr |
| Indoor Source | Combustion-related particles smoking, cooking, use of a wood stove or fireplace, use of candles or incense, gas or kerosene space heaters or stoves. |
| Personal Method | NR |

| | |
|------------------------------|--|
| Personal Size | NR |
| Microenvironment Size | 0.10 µg-5 µg; (see note below) |
| Ambient Size | PM _{2.5} |
| Component(s) | NR |
| Primary Findings | Geometric mean values of indoor concentrations in the seven locations differed by less than a factor of 2, and the shape of the distributions was very similar across cities, both for the nominal 2-week averages and for hourly averages. The hourly averages exceeded 100 µg/m ³ for at least 2% of all measurements in all cities, and exceeded 1,000 µg/m ³ on at least a few occasions in each city. The most important particle source in these homes was smoking. A second, less powerful source was cooking, particularly frying/ sautéing or reporting a smoky cooking event. Use of incense also led to significant increases in particle concentrations. Dusting frequently also led to higher concentrations, possibly considerably higher than indicated by the pDR because of its lack of sensitivity for coarse particles. Infiltration of outdoor air added about half of the outdoor air concentration to the concentrations produced by the indoor sources, a result similar to that found by previous studies. Most of the observed variance in indoor concentrations was day to day, with roughly similar contributions to the variance from visit to visit and home to home within a city and only a small contribution made by variance among cities. The small variation among cities and the similarity across cities of the observed indoor air particle distributions suggest that sources of indoor concentrations do not vary considerably from one city to the next, and thus that simple models can predict indoor air concentrations in cities having only outdoor measurements. A new finding from this study was the observation that concentrations of fine particles peak in the late evening in homes with smoking, perhaps reflecting the influence of after dinner smoking. |

Williams et al. (2003, [053338](#))

| | |
|------------------------------|---|
| Study Design | Cohort study, longitudinal |
| Period | Summer 2000, fall 2000, winter 2001, and spring 2001 |
| Location | SE Raleigh, North Carolina; Chapel Hill, North Carolina |
| Population | Elderly persons |
| Age Groups | 50 yr |
| Indoor Source | NR. While no smokers were enrolled into the study, 18 participants occasionally recorded passive exposures to environmental tobacco smoke. Since this study attempted to determine the effects of ambient PM upon personal and residential settings, and ETS exposures typically overwhelm ambient contributions, gravimetric values believed to have been heavily influenced by ETS were excluded from the analysis. |
| Personal Method | A number of filter-based PM monitors widely used in other PM studies were employed here as described below in Table 1. A nylon vest, matched to the body size of the participant, was used to support and retain all of the personal monitoring equipment. All of the personal monitoring equipment was located in the participants breathing zone (chest area) with the exception of the nephelometer which was secured to the front pocket of the vest with the inlet fully exposed. Each participant was asked to wear the vest at all times with the exception of sleeping, bathing or the changing of clothes. In those instances, they were asked to secure the vest on nearby furniture or fixture. A local State of North Carolina AIRS monitoring platform in Raleigh, NC was selected to serve as the ambient monitoring site. |
| Personal Size | PM _{2.5} |
| Microenvironment Size | PM _{2.5} ; PM ₁₀ ; PM _{10-2.5} |
| Ambient Size | PM _{2.5} ; PM ₁₀ ; PM _{10-2.5} |
| Component(s) | NR |
| Primary Findings | No statistical difference in personal PM _{2.5} concentration exposures existed between the two cohorts. Neither seasonality nor community settings were determined to be critical factors in aggregate personal PM _{2.5} exposures in the two subpopulations. PM _{2.5} , and to a lesser extent PM ₁₀ , mass concentrations were determined to be generally homogeneous across a large spatial area. The lack of a seasonal effect observed in the RTP was unexpected due to the historically higher PM _{2.5} levels observed in central North Carolina during the spring and summertime when automotive traffic is highest and regional power plant demands for electricity are greatest (and subsequent release of emissions). PM _{2.5} personal cloud estimates in the current study were in agreement with those observed in other PM studies involving susceptible subpopulations having more sedentary lifestyles. Mean personal PM _{2.5} exposures in the current study had a moderate Pearson correlation relative to ambient or residential outdoor mass concentrations i |

| Ambient Size | Nonrefractory-PM1 |
| Component(s) | Sulfate, Ammonium, Nitrate, Organics, Chloride |
| Primary Findings | Reasonably good agreement was observed on particle concentrations, composition, and size distributions between the AMS data and measurements from co-located instruments (given the difference between the PM ₁ and PM _{2.5} size cuts), including TEOM, semicontinuous sulfate, 2-h- and 24-h-averaged organic carbon, SMPS, 4-h-averaged ammonium, and micro-orifice uniform deposit impactor. |

Zhao et al. (2006, [156181](#))

| | |
|------------------------------|---|
| Study Design | Aerosol source apportionment under four environments (personal, residential indoor, residential outdoor and ambient) to evaluate the relationship between different environments through exposure analysis, and to demonstrate the utility of the combined receptor model on air quality studies of various environments. |
| Period | June 2000 to May 2001 |
| Location | Raleigh and Chapel Hill, NC |
| Population | NR. People with respiratory ailments most likely. |
| Age Groups | NR |
| Indoor Source | Yes (4 main sources to residential indoor PM Cu-factor mixed with indoor soil, secondary sulfate, Personal care and activity, ETS and its mixture) |
| Personal Method | Personal Exposure Monitors (PEM) and Harvard Impactor monitors (HI) |
| Personal Size | NR |
| Microenvironment Size | NR |
| Ambient Size | NR |
| Component(s) | OC, EC, and elements |
| Primary Findings | As per the authors "Secondary sulfate was the largest source for both residential outdoor and ambient PM. Cooking and personal care activity were two major internal sources for personal and residential indoor PM samples. In this study, secondary sulfate and motor-vehicle emission contributed significantly to the personal and residential indoor PM. |

Zhao et al. (2007, [156182](#))

| | |
|------------------------------|--|
| Study Design | Comprehensive analysis of the sources of PM ₁₀ exposure on children with moderate to severe asthma in urban-poor settings. |
| Period | Two winter periods (October 2002-March 2003 and October 2003-March 2004) |
| Location | Elementary school for children with significant asthma, Denver, CO |
| Population | Schoolchildren in urban-poor settings suffering from moderate to severe asthma |
| Age Groups | 6-13 yr (60% in the range 10-13 yr, rest in the range 6-9 yr) |
| Indoor Source | Yes, House cleaning compounds, and smoking were identified as primary internal sources. |
| Personal Method | Personal Exposure Monitor (PEM) |
| Personal Size | PM _{2.5} |
| Microenvironment Size | PM _{2.5} |
| Ambient Size | PM _{2.5} |
| Component(s) | EC, Cl, Si, NO ₃ |
| Primary Findings | Four external sources and three internal sources were resolved in this study. Secondary nitrate and motor vehicle were two major outdoor PM _{2.5} sources. Cooking was the largest contributor to the personal and indoor samples. Indoor environmental tobacco smoking also has an important impact on the composition of the personal exposure samples. |

Zhu et al. (2005, [157191](#))

| | |
|------------------------------|---|
| Study Design | 4 apartments near the freeway were monitored at 2 times for 6 consecutive days, 24 h per day. Subjects did not enter the bedrooms where the samplers were, no cooking, cleaning, children, or pets. |
| Period | Oct. 2003-Dec. 2003 and Dec. 2003-Jan. 2004 |
| Location | Los Angeles, CA |
| Population | Urban Populations near major freeways. |
| Age Groups | NR |
| Indoor Source | NR |
| Personal Method | NR |
| Personal Size | Indoor and Outdoor ultrafine particles (6-220 nm) |
| Microenvironment Size | NR |
| Component(s) | CO |
| Primary Findings | The size distributions of indoor aerosols showed less variability than the adjacent outdoor aerosols. Indoor to outdoor ratios for ultrafine particle concentrations depended strongly on particle size. I/O ratios were dependent on the indoor ventilation mechanisms |

applied. Size-dependent particle penetration factors and deposition rates were predicted from data by fitting a dynamic mass balance model.

Zöllner et al. (2007, [157192](#))

| | |
|------------------------------|---|
| Study Design | PM exposure was investigated in and outside of schools |
| Period | Winter Period of 2005 and 2006 |
| Location | Baden-Wuerttemberg, Germany |
| Population | School children |
| Age Groups | NR |
| Personal Method | No personal monitoring done. PM _{2.5} was collected with filter device LVS 6.01 and analyzed gravimetrically; fifteen particle fractions (0.30 µm to >20 µm) were recorded with laser particle counters; >0.02 µm particles were recorded using condensation particle counters |
| Personal Size | NR |
| Microenvironment Size | They only reported concentrations for PM _{2.5} . PM 0.02 to >20 were collected and analyzed but only PM _{2.5} concentration were reported. |
| Ambient Size | They only reported concentrations for PM _{2.5} . PM 0.02 to >20 were collected and analyzed but only PM _{2.5} concentration were reported. |
| Primary Findings | 1) The impact of PM was strongly influenced by specific weather conditions; 2) Time resolution of measurements in classrooms showed variation in particle concentration depending on the type of building and indoor activities; 3) Concentrations of very small particles indoors and in ambient air measured by condensation particle counter were influenced by traffic emissions. |

1

Table A-53. Examples of studies showing developments with UFP sampling methods since the 2004 PM AQCD.

| Reference | PM Size Ranges | PM Constituents | Instruments | Primary Findings |
|---|----------------|-------------------------|---|--|
| Biswas et al. (2005, 150694) | | | CPC (water) | Water-based CPC performance eval |
| Feldpausch et al. (2006, 155773) | 20 – 100 nm | Carbonaceous aerosols | DS with CPC, compared with DMA | The DS with CPC compared fairly well with the DMA for particle sizes up to 40 nm with 20 – 40% underestimation depending on discharge frequency settings. The DS sampling period is 3 – 5 s in comparison with the 1 min scanning time of the DMA. |
| Hering et al. (2005, 155838) | | | CPC (water) | Water-based CPC performance eval |
| Hermann et al. (2007, 155840) | 3 – 40 nm | Ag, NaCl | CPC (water and butanol) | Roughly 95% collection efficiency for d > 5 nm for TSI models 3776 and 3786, 95% efficiency for d > 20 nm for model 3775, near 90% efficiency for d > 20 nm for model 3785, near 90% efficiency for d > 25 nm for model 3772. |
| Kinsey et al. (2006, 130654) | 10 nm – 5 µm | DE | TEOM, SMPS, CPC, DustTrak, E-BAM, ELPI, integrated filter samples | TEOM best comparison with gravimetric filter among mass concentration analyzers, ELPI and SMPS comparable for differential number distribution but ELPI not useful for gravimetric analysis because mass is not significant at small end of distribution. |
| Kulmala et al. (2007, 097838) | | | CPC | Changing temperature difference between saturator and condenser within CPC allowed for differences in cut-off diameters. |
| Kulmala et al. (2007, 155911) | 2 – 20 nm | Atmospheric aerosol, Ag | Battery of CPCs (water, butanol, n-butanol) | Used the battery to discriminate between water-soluble, water-insoluble, butanol-soluble, and butanol-insoluble nucleation-mode particles |
| Ntziachristos and Samaras (2006, 116722) | 7 nm – 1 µm | Automobile exhaust | 5 instruments used simultaneously to reduce uncertainty: Teflon-coated filter downstream of constant volume sampling, ELPI with thermodenuder, CPC, SMPS, diffusion charger | Use of four reduced variables combining output from all instruments (ratio of particle number concentration from CPC and ELPI, estimated mean geometric mobility diameter from signal of diffusion charger and number concentration from CPC, ratio of signal of diffusion charger to constant volume sampler mass, ratio of constant volume sampler mass to volume collected by ELPI) resulted in identification of clear outliers and factors related to driving and fuel properties rather than measurement errors. |
| Olfert et al. (2008, 156004) | 30 – 100 nm | NaCl, ambient | FIMS (compared with SMPS) | Particle number concentrations reported by the FIMS were 8 – 23% higher than the SMPS using an inversion technique designed to correct for particle residence time in the FIMS, which operates at 0.1 s resolution. |

| Reference | PM Size Ranges | PM Constituents | Instruments | Primary Findings |

| Petäjä et al. (2006, 156021) | | | CPC (water) | Water-based CPC performance eval |
| Winkler et al. (2008, 156160) | 1.5 – 4 nm | Tungsten oxide | CPC (n-Propanol) | Authors remove excess charge on particles with ion trap to detect particles down to ~ 1 nm (by eliminating electrostatic attraction to agglomerate). |

Table A-54. Summary of in-vehicle studies of exposure assessment.

| Reference | Study Design | Mode of Transport | Exposures | Primary Findings |
|--|--|--------------------|--|--|
| Rossner et al. (2008, 156927) | Measured PM _{2.5} exposure of 50 city bus drivers and 50 controls in Prague, Czech Republic using personal samplers (type not specified) and VOCs using passive samplers. PM _{2.5} filters analyzed for c-PAHs. Focus of study is oxidative stress biomarkers in drivers. Study period: winter 2005, summer 2006, winter 2006. | Bus | Units: ng/m ³ winter 2005: Bus c-PAH 7.1 (3.7) B[a]P 1.3 (0.7) summer 2006: c-PAH 1.8 (0.5) B[a]P 0.2 (0.1) winter 2006: Bus c-PAH 5.4 (3.5) B[a]P 1.0 (0.5) | c-PAH and B[a]P exposure to bus drivers was significantly higher in Winter 2006, but control exposure was significantly higher in Winter 2005 for c-PAH and B[a]P and in summer 2006 for c-PAH. No significant difference in VOC exposure between bus drivers and controls was observed. Oxidative stress markers were significantly higher in bus drivers than controls for all seasons. |
| Fruin et al. (2008, 097183); Westerdahl et al. (2005, 086502) [Note: same data presented.] | On-road zero emissions vehicle driven on 33-mi arterial road and 75-mi freeway was equipped measured UFP (CPCs, SMPS, EAD), BC (aethalometer), NO _x (chemiluminescence), PM-bound PAHs (UV-photoionization), CO (Q-Trak). DVD analysis of traffic density and car speed. Study Period: Feb-Apr 2003 for 2- to 4-h periods. | Car | Arterial range of medians: UFP (1000p/cm ³) 13-43 PM _{2.5} (µg/m ³) 7.9-45 BC (µg/m ³) 0.74-3.3 Freeway range of medians: UFP (1000p/cm ³) 47-190 PM _{2.5} (µg/m ³) 25-110 BC (µg/m ³) 2.4-13 | Measurements of freeway UFP, BC, PM-bound PAH, and NO concentrations were roughly one order of magnitude higher than ambient measurements. Multiple regression analysis suggests these concentrations were a function of truck density and total truck count. (Only PM measurements reported here). |
| Briggs et al. (2008, 156294) | UFP (P-Trak) and PM ₁₀ , PM _{2.5} , and PM ₁ (OSIRIS light scatter) were operated in a car while driving or walking on one of 48 routes in London. Trips ranged 1.5-15 min by car and were repeated up to 5 times to improve statistics. Study Period: Weekdays in May and June 2005. | Car Walking | Units: PM ₁ – PM ₁₀ (µg/m ³), UFP (p cm-3) Avg Car Exposure: PM ₁₀ 5.87 (3.09) PM _{2.5} 3.01 (1.10) PM ₁ 1.82 (1.10) UFP 21639 (14379) Avg Walking Exposure: PM ₁₀ 27.56 (13.16) PM _{2.5} 6.59 (3.12) PM ₁ 3.37 (3.40) UFP 30334 (17245) | In-car concentrations of PM _{2.5} , PM ₁ , and UFP correlated well with walking concentrations (R = 0.806, 0.800, 0.799 respectively). Avg walking concentrations were 1.4 – 4.7 times higher than avg in-car concentrations. Cumulative walking exposures (not shown here) were 4.4 – 15.2 times higher than those in cars, likely resulting from longer transit times for walking. |

|--|--|------------------------------|--|---|
| Gomez-Perales et al. (2007, 138816) | PM _{2.5} (personal filter pump), CO (T15 electrochemical cell), and benzene (canister) were measured on transit routes, and PM _{2.5} filters were analyzed for mass, OC/EC, SO ₄ ²⁻ , NO ₃ ⁻ , and trace metals. Study period: 3-h morning and evening rush hour Jan – March 2003 | Bus Minibus Metro | Units: PM _{2.5} mass (µg/m ³), components (% of mass) | Buses and minibuses had similar concentration levels for PM _{2.5} mass, and metro exposures were lower. CO and benzene concentrations were higher on minibuses than buses. OC was the largest PM constituent for all modes of transport. Measured concentrations were higher in the morning than in the evening rush hour periods. Maximum historical wind speeds (1995-2003) appeared to be inversely associated with measured concentration. |

| Sabin et al. (2005, 088300) | BC (aethalometer), particle-bound PAH (UV-photoionization), and NO (luminol reaction) were measured on 3 diesel school buses, 1 diesel school bus with a particle trap, and one compressed gas bus during before- and after-school commutes. Study Period: May – June 2002. | School bus (diesel, diesel with particle trap (TO), compressed gas (CNG)) | In-bus mean concentration, Units: BC ($\mu\text{g}/\text{m}^3$), PAH (ng/m^3) | Mean concentrations on diesel buses without newer emissions control technologies were 2 – 4.4 times higher than background. On buses with particle traps, concentrations were 1.2 – 2.5 times higher than background, while concentrations on compressed gas-fueled school buses were actually lower than background. |

| Adgate et al. (2007, 156196) | Personal, Micro, and Ambient: PM _{2.5} - broken down into TE | Ag, Al, Ca, Cd, Co, Cr, Cs, Cu, Fe, K, La, Mg, Mn, Na, Ni, Pb, S, Sb, Sc, Ti, Tl, V, Zn | Median, units: ng/m ³ : O I P S 334.4 272.1 351.6; Ca 232.285.0 174.1; Al 96.3 23.3 58.6; Na 33.1 20.6 31.9; Fe 12.6 43.1 78.6; Mg 10.9 16.3 27.5; K 3.2 38.4 47.5; Ti 3.0 0.8 1.4; Zn 2.7 6.5 9.6; Cu 2.4 1.5 4.9; Ni NA -0.1 1.8; Pb 1.5 2.4 3.2; Mn 0.6 1.5 2.3; Sb 0.08 0.21 0.30; Cd 0.05 0.12 0.14; V 0.05 0.12 0.16; La 0.02 0.05 0.11; Cs 0.00 0.00 0.00; Th 0.00 0.00 0.00; Sc 0.00 0.00 0.01; Ag 0.00 0.07 0.08; Co NA 0.02 0.07; Cr -0.09 1.2 2.6 | The relationships among P, I, and O concentrations varied across TEs. Unadjusted mixed-model results demonstrated that O monitors are more likely to underestimate than overestimate exposure to many of the TEs that are suspected to play a role in the causation of air pollution related health effects. These data also support the conclusion that TE exposures are more likely to be underestimated in the lower income and centrally located PHI community than in the comparatively higher income BC K community. Within the limits of statistical power for this sample size, the adjusted models indicated clear seasonal and community related effects that should be incorporated in long-term exposure estimates for this population. |

| Jansen et al. (2005, 082236) | Personal: PM ₁₀ Micro: PM ₁₀ , PM _{2.5} , fine particles (~ PM ₁) Ambient: PM ₁₀ , PM _{2.5} | BC, as an estimate of elemental carbon (EC) | Mean (IQ Range), units: µg/m ³ : BC Indoor: 1.34 (1.12) Outdoor 2.01 (1.68) Personal 1.64 (2.05) | For 7 subjects with asthma, a 10 µg/m ³ increase in 24-h avg outdoor PM ₁₀ and PM _{2.5} was associated with a 5.9 [95% CI, 2.9–8.9] and 4.2 ppb (95% CI, 1.3–7.1) increase in FENO, respectively. A 1 µg/m ³ increase in outdoor, indoor, and personal BC was associated with increases in FENO of 2.3 ppb (95% CI, 1.1–3.6), 4.0 ppb (95% CI, 2.0–5.9), and 1.2 ppb (95% CI, 0.2–2.2), respectively. No significant association was found between PM or BC measures and changes in spirometry, blood pressure, pulse rate, or SaO ₂ in these subjects. |
| Sørensen et al. (2003, 157000) | Personal: PM _{2.5} Micro: NR Ambient: PM _{2.5} | BS (black smoke) | Units: 10 ⁻⁶ /m n Median Q25-Q75 All 177 6.8 (5.0-13.2) Autumn 42 7.1 (6.5-17.2) Winter 46 8.2 (5.1-13.3) Spring 46 12.6 (5.4-10.4) Summer 47 8.1 (3.4-9.0) | Personal PM _{2.5} exposure was found to be a predictor of 8-oxodG in lymphocyte DNA. No other associations between exposure markers and biomarkers could be distinguished. ETS was not a predictor of any biomarker in the present study. The current study suggests that exposure to PM _{2.5} at modest levels can induce oxidative DNA damage and that the association to oxidative DNA damage was confined to the personal exposure, whereas the ambient background concentrations showed no significant association. For most of the biomarkers and external exposure markers, significant differences between the seasons were found. Similarly, season was a significant predictor of SBs and PAH adducts, with avg outdoor temperature as an additional significant predictor. |
| Molnár et al. (2005, 156772) | Personal: 2.5 Micro and Ambient: PM _{10-2.5} and PM _{2.5} | BS (black smoke) S Cl K Ca | Median, unit = ng/m ³ Wood burners Ref 1-sided p-value BS 0.97 0.74 0.053 | Statistically significant contributions of wood burning to personal exposure and indoor concentrations have been shown for K, Ca, and Zn. Increases of |

| | | Mn Fe Cu Zn Br Rb Pb | S 880 650 0.500 Cl 200 160 0.036 K 240 140 0.024 Ca 76 43 0.033 Mn 4.8 3.5 0.250 Fe 64 49 0.139 Cu 8.9 2.4 0.016 Zn 38 22 0.033 | 66–80% were found for these elements, which seem to be good wood-smoke markers. In addition, Cl, Mn, Cu, Rb, Pb, and BS were found to be possible wood-smoke markers, though not always to a statistically significant degree for personal exposure and indoor concentrations. For some of these elements subgroups of wood burners had clearly higher levels which could not be explained by the information available. Sulphur, one of the more typical elements mentioned as a wood-smoke marker, showed no relation to wood smoke in this study due to the large variations in outdoor concentrations from LDT air pollution. This was also the case for PM _{2.5} mass. Personal exposures and indoor levels correlated well among the subjects for all investigated species, and personal exposures were generally higher than indoor levels. The correlations between the outdoor and personal or ind |
| Johannesson et al. (2007, 156614) | Personal, Micro, and Ambient: PM _{2.5} , PM1 | BS- Black Smoke | BS2.5 Mean SD Personal 0.65 0.47 Exclusively smokers 0.62 0.47 Residential indoor 0.56 0.47 Exclusively smokers 0.52 0.46 Residential outdoor 0.68 0.51 Exclusively smokers 0.71 0.54 Urban background 0.63 0.37 All measurements 0.68 0.40 PM1/BS1 Personal 0.55 0.20 Residential indoor 0.54 0.45 Exclusively smokers 0.49 0.43 Residential outdoor 0.66 0.51 Exclusively smokers 0.68 | Personal exposure of PM _{2.5} correlated well with indoor levels, and the associations with residential outdoor and urban background concentrations were also acceptable. Statistically significantly higher personal exposure compared with residential outdoor levels of PM _{2.5} was found for nonsmokers. PM1 made up a considerable proportion (about 70–80%) of PM _{2.5} . For BS, significantly higher levels were found outdoors compared with indoors, and levels were higher outdoors during the fall than during spring. There were relatively low correlations between particle mass and BS. The urban background station provided a good estimate of the residential outdoor concentrations of both PM _{2.5} and BS2.5 within the city. The air mass origin affected the outdoor levels of both PM _{2.5} and BS2.5; however, no effect was seen on personal exposure or indoor levels. |

| Na and Cocker (2005, 156790) | Personal: PM _{2.5} Micro: NR Ambient: PM _{2.5} | EC (Elemental carbon) OC (Organic carbon) | Mean (SD), units = µg/m ³ Residential homes: EC 2.0 (NR) OC 14.8 (NR) High school (EC): Weekday samples 1.1 (0.9) Weekend samples 1.0 (0.5) High school (OC): Weekday samples 8.8 (4.7) Weekend samples 7.4 (2.4) | Indoor PM _{2.5} was significant influenced by indoor OC sources. Indoor EC sources were predominantly of outdoor origin. |
| Geyh et al. (2005, 186949) | Personal: TD, PM ₁₀ , PM _{2.5} Micro: NR Ambient: TD, PM ₁₀ , PM _{2.5} | EC OC VOC also assessed | Mean (SD), units = µg/m ³ : Summary Statistics by Area Location October 2001: Albany and West EC 5.9 (NA) OC 36 (NA) Liberty and Greenwich EC 5.3 (59) OC 30 (56) Park Place and Greenwich EC 14.5 (5.4) OC 72 (26) Church and Dey EC 7.9 (3.3) OC 48 (15) April 2002: Liberty and West EC 4.2 (2.1) OC 26 (13) Barclay and Greenwich EC 4.0 (2.6) OC 18 (14) Church and Dey EC 4.5 (1.9) OC 27 (15) Middle of the Pile EC 6.7 (1.0) OC 40 (25) | During October, the median personal exposure to TD was 346 µg/m ³ . The maximum area concentration 1742 µg/m ³ , was found in the middle of the debris. The maximum TD concentration found at the perimeter was 392 µg/m ³ implying a strong concentration gradient from the middle of debris outward. PM _{2.5} /PM ₁₀ ratios ranged from 23% to 100% suggesting significant fire activity during some of the sampled shifts. During April, the median personal exposure to TD was 144 µg/m ³ , and the highest area concentration, 195 µg/m ³ , was found at the perimeter. Although the overall concentrations on PM at the site were significantly lower in April, the relative contributions of fine particles to the PM ₁₀ , and EC and OC to the TD were similar. During both months, volatile organic compounds concentrations were low. Comparison of recorded EC and OC values from October 2001 and April 2002 with previous studies suggests that the primary source of exposure to EC for the WTC truck drivers was emissions from their own vehicles. |
| Zhao et al. (2007, 156182) | Personal, Micro, and Ambient: PM _{2.5} | EC, Cl, Si, NO ₃ | Units = µg/m ³ : Personal: EC: 1.64 NO ₃ : 0.135, Si: 0.176, Cl: 0.116; Indoor: EC: 1.819 NO ₃ : 0.013, Si: 0.051, Cl: 0.024; Outdoor: EC: 1.876 NO ₃ : 0.292, Si: 0.115, Cl: 0.013 | Four external sources and three internal sources were resolved in this study. Secondary nitrate and motor vehicle were two major outdoor PM _{2.5} sources. Cooking was the largest contributor to the personal and indoor samples. Indoor environmental tobacco smoking also has an important impact on the composition of the personal exposure samples. |
| Meng et al. (2005, 081194) | Personal: PM _{2.5} Micro: NA Ambient: NR | EC, OC, S, Si | Mean (SD), units = ng/m ³ : Indoor: EC: 1165.9 (2081.0) OC: 7725.5 (9359.3) S: 902.3 (602.2) Si: 124.0 (79.0) | Use of central-site PM _{2.5} as an exposure surrogate underestimates the bandwidth of the distribution of exposures to |

| Koutrakis et al. (2005, 095800) | Personal: PM _{2.5} Micro: NR Ambient: PM _{2.5} | Elemental Carbon (EC), SO ₄ ²⁻ | Mean (SD) data are provided for Baltimore and Boston, units = µg/m ³ : EC: (Baltimore, Boston) Winter: Seniors: NR, 1.4 (0.9) Children: 2.8 (1.8), 1.6 (1.6) COPD: 2.0 (1.2), NR SO ₄ : (Baltimore, Boston) Winter: Seniors: 1.9 (1.1), 1.9 (1.2) Children: NR, 2.3 (1.7) COPD: 1.5 (0.8), NR Summer: Seniors: 5.7 (3.5), 2.9 (1.9) | Ambient PM _{2.5} and SO ₄ are strong predictors of respective personal exposures. Ambient SO ₄ is a strong predictor of personal exposure to PM _{2.5} . Because PM _{2.5} has substantial indoor sources and SO ₄ does not, the investigators concluded that personal exposure to SO ₄ accurately reflects exposure to ambient PM _{2.5} and therefore the ambient component of personal exposure to PM _{2.5} as well. |
| Chillrud et al. (2004, 054799) | Personal: PM _{2.5} Micro: PM _{2.5} Home indoor and home outdoor Ambient: Urban fixed-site and upwind fixed site operated for three consecutive 48-h periods each week. | Elemental iron, manganese, and chromium are reported in this study out of 28 elements sampled. | Mean of duplicate samples: PM _{2.5} : 62 µg/m ³ Fe: 26 µg/m ³ Mn: 240 ng/m ³ Cr: 84 ng/m ³ Variability: 1-15% | Personal samples had significantly higher concentration of iron, manganese, and chromium than home indoor and ambient samples. The ratios of Fe (ng/µg of PM _{2.5}) vs Mn (pg/µg PM _{2.5}) showed personal samples to be twice the ratio for crustal material. Similarly for the Cr/Mn ratio. The ratios and strong correlations between pairs of elements suggested steel dust as the source. Time-activity data suggested subways as a source |

| Kulkarni and Patil (2003, 156664) | Personal: PM ₅ Micro: NR Ambient: PM ₅ | Lead Nickel Cadmium Copper Chromium Potassium Iron Manganese | Personal samples: Mean ± SD Type Lead Occupational 4.384 ± 7.766 µg/m ³ Residential 4.093 ± 5.925 µg/m ³ 24-h integrated 4.205 ± 1.523 µg/m ³ Cadmium Occupational 0.201 ± 0.158 µg/m ³ Residential 0.111 ± 0.165 µg/m ³ 24-h integrated 0.134 ± 0.140 µg/m ³ Manganese Occupational 1.979 ± 7.842 µg/m ³ Residential 0.180 ± 0.261 µg/m ³ 24-h integrated 1.983 ± 6.824 µg/m ³ Potassium Occupational 3.473 ± 4.691 µg/m ³ | All listed metals were detected in the ambient air where as only Lead, Cadmium, Manganese, and Potassium were detected in personal exposures. Mean daily exposure to lead exceeds the Indian NAAQS by a factor of 4.2. However, ambient concentration of lead conforms to this standard. There is a rising trend in the personal exposures and ambient levels of cadmium. However, they are low and do not pose any major health risk as yet. Personal exposures to toxic metals exceed the corresponding ambient levels by a large factor ranging from 6.1 to 13.2. Thus, ambient concentrations may underestimate health risk due to personal exposure of toxic metals. Outdoor exposure to toxic metals is greater than the indoor (ratios ranging from 2.3 to 1.1) except for potassium (ratio 0.77). However, there is no significant correlation between these two. |

To study relationships between PM_{2.5} exposure and emission sources.</p> <p>Methods: Expanded receptor model.</p> <p>Subjects: Nonsmoking, ambulatory, ≥50yrs. 2 cohorts: mostly Caucasian with implanted cardiac defibrillators in Chapel, NC; 30 African-Americans with controlled hypertension in low-to-moderate SES neighborhoods in Raleigh, NC. 7d/season, 4 seasons in 2000-2001.</p> | n/a | n/a |
| Zhu et al. (2005, 190081) | <p>Objective: To determine penetration behavior of outdoor ultrafine particles into indoor environments in areas close to freeways.</p> <p>Methods: Dynamic mass balance model.</p> <p>Subjects: 4 2-bedroom apartments within 60m from the center of the 405 Freeway in Los Angeles, CA. Non-smoking tenants. 2 sampling periods (non-cooking, non-cleaning): Oct.-Dec. 2003 and Dec. 2003-Jan. 2004.</p> | n/a | <p>Highest (largest ultrafine particles- 70-100nm): 0.6-0.9</p> <p>Lowest (smallest ultrafine particles- 10-20nm): 0.1-0.4</p> |

1. I/O estimated from Figure 8 in study.
2. I/O calculated from indoor and outdoor concentrations in Table 1 in study.
3. F_{inf} measured by coefficient of determination, R^2 .
4. RIOPA calculated I/O's.
5. I/O calculated from mean and median indoor and outdoor concentrations listed in Table 1 of study.
6. I/O's estimated from Figure 3 in study.
7. Mean and median I/O concentrations calculated from all residences in study.
8. F_{inf} estimated from Figure 2 in study.
9. F_{inf} presented in box plot (Figure 8), however data is difficult to deduce. No numeric values reported.

Table A-55. Summary of PM – copollutant exposure studies.

| Reference | PM metric | Copollutant metric | Association between PM and copollutant | Primary findings |
|---|--|--|---|---|
| Fruin et al. (2008, 097183) | In-vehicle UFP, BC, PM-bound PAH | In-vehicle NO _x , CO | <p>R UFP PM_{2.5} NO BC CO CO₂</p> <p>UFP 1 0.71 0.97 0.95 0.63 0.72</p> <p>PM_{2.5} 1 0.69 0.89 0.66 0.68</p> <p>NO 1 0.91 0.78 0.85</p> <p>BC 1 0.65 0.74</p> <p>CO 1 0.94</p> <p>CO₂ 1</p> <p>Note that these correlations are computed from data presented by Fruin et al. (2008, 097183) for mean concentrations at different locations.</p> | Measurements of freeway UFP, BC, PM-bound PAH, and NO concentrations were roughly one order of magnitude higher than ambient measurements. Multiple regression analysis suggests these concentrations were a function of truck density and total truck count. |
| Schwartz et al. (2007, 090220) | Ambient and personal PM _{2.5} data from the Baltimore panel study | Ambient and personal O ₃ and NO ₂ data from the Baltimore panel study. | <p>Median β for regressions:</p> <p>Ambient PM_{2.5} Ambient O₃ Ambient NO₂</p> <p>Personal PM_{2.5} 0.0143 - 0.0016 0.0115</p> <p>Personal PM_{2.5} of ambient origin 0.0183 -0.0037 0.0124</p> <p>Personal SO₄²⁻ 0.0051 0.0035 0.0006</p> <p>Personal O₃ 0.0014 0.0010 0.0009</p> <p>Personal NO₂ 0.0015 0.0009 0.0010</p> | Results suggest that ambient O ₃ exposure may be related to personal SO ₄ ²⁻ exposure but not to personal PM _{2.5} exposure on the whole. Ambient NO ₂ exposure was associated with personal PM _{2.5} exposure, possibly because both have traffic sources. |

| Reference | PM metric | Copollutant metric | Association between PM and copollutant | | | | | | Primary findings |
|--|---|--|--|-------------------|-----------------|-----|-----------------|-----|---|
| Tolbert et al. (2007, 090316) | Ambient PM ₁₀ , PM _{10-2.5} , PM _{2.5} , EC, OC, TC, SO ₄ ²⁻ , water-soluble metals, oxygenated hydrocarbons | Ambient O ₃ , NO ₂ , CO, SO ₂ | PM ₁₀ | O ₃ | NO ₂ | CO | SO ₂ | | Low correlations were seen between SO ₂ and PM constituents. Components were used in a multi-pollutant model to predict emergency department visits in Atlanta. CO was found to be the most significant predictor of cardiovascular disease visits in one-, two-, and three-pollutant models, and O ₃ was the most significant predictor of respiratory disease visits in one-, two-, and three-pollutant models. |

| Reference | PM metric | Copollutant metric | Association between PM and copollutant | Primary findings |
|---|---|---|---|---|
| Brook et al. (2007, 091153) | Ambient PM ₁₀ , PM _{10-2.5} , PM _{2.5} , SO ₄ ²⁻ , and trace metals in 10 Canadian cities. | Ambient NO ₂ , NO | R with NO ₂ (min, Max) NO ₂ 1.00 (1.00, 1.00) NO 0.67 (0.51, 0.77) PM _{2.5} 0.54 (0.45, 0.71) PM _{10-2.5} 0.31 (0.04, 0.50) PM _{10-0.50} (0.23, 0.70) SO ₄ ²⁻ 0.33 (0.10, 0.48) Fe 0.44 (0.29, 0.56) Zn 0.39 (0.28, 0.52) Ni 0.20 (0.06, 0.40) Mn 0.51 (0.37, 0.62) As 0.21 (0.07, 0.39) Al 0.07 (-0.17, 0.18) Cu 0.03 (-0.07, 0.15) Pb 0.28 (0.16, 0.39) Si 0.19 (0.00, 0.32) Se 0.14 (-0.04, 0.35) | NO ₂ showed the strongest association with mortality, but it is unclear if this association is due to health effects of NO ₂ or health effects of copollutant PM. |
| Ito et al. (2007, 156594) | Ambient PM _{2.5} | Ambient O ₃ , NO ₂ , SO ₂ , CO | Shown in figure format only. | Authors tested relationship between meteorological variables and copollutants to determine if multi-pollutant models are impacted by spatial or temporal variation or by meteorological conditions. Multicollinearity varied by pollutant and season. |
| Kaur et al. (2005, 086504) | Fixed-site and personal PM _{2.5} , personal UFP | Fixed site and personal CO | Personal R: PM _{2.5} UFP CO PM _{2.5} 1 0.5 0.2 UFP 0.5 1 0.7 CO 0.2 0.7 1 | Fairly low correlation was observed between PM _{2.5} and CO and between PM _{2.5} and UFP, stronger correlations between UFP and CO. |
| Kaur et al. (2005, 088175) | Fixed-site and personal PM _{2.5} analyzed post-sample for light absorbance (as indicator for carbonaceous aerosol), personal UFP | Fixed site and personal CO | Personal R: R PM _{2.5} Abs CO UFP PM _{2.5} 1 0.3 -0.1 0.0 Abs 0.3 1 0.2 0.7 CO -0.1 0.2 1 0.1 UFP 0.0 0.7 0.1 1 | Strongest correlation observed between UFP and absorption, which is reasonable given that much absorptive carbonaceous aerosol is in the ultrafine range. |
| Sorenson et al. (2005, 089428) | Personal, indoor residential, and outdoor residential PM _{2.5} and BC | Personal, indoor residential, and outdoor residential NO ₂ | Personal exposure regression coefficients to: PM _{2.5} BC NO ₂ Bedroom 0.72 0.47 0.70 Front door 0.46 0.61 0.60 Background 0.29 0.03 0.56 | Personal NO ₂ concentration is more strongly influenced by background than PM _{2.5} or BC. |
| Sabin et al. (2005, 087728) | BC, particle-bound PAH on a school bus. | NO ₂ on a school bus. | BC PB-PAH NO ₂ BC 1 0.94 0.49 PB-PAH 1 0.37 NO ₂ 1 Note that these correlations are computed from data presented by Sabin et al. for mean concentrations when the test bus travelled behind different vehicles. | Less correlation was observed between NO ₂ and PM species. This study was aimed more at fuel choices and control technologies for children's exposures on school buses. |

Table A-56. Summary of studies relating PM, SES, and mortality and/or morbidity.

| Reference | Population Studied | Data interval | Metrics Used (health; pollutant; SES variable) | Study Outcome |
|--|--|---------------|--|---|
| Bateson and Schwartz (2004, 086244) | Residents (> 65) of Cook Co. IL with prior cardiac or respiratory hospitalization, 1988-1991 | Days | All-cause mortality; PM ₁₀ ; median household income, % with bachelor's degree, % not speaking English at home | No significant change in mortality with a 10 µg/m ³ increase in PM ₁₀ with SES variables. |
| Cifuentes et al. (2000, 010351) | Residents (aged 25-64) of Santiago, Chile, 1988-1996 | Days | Non-trauma mortality; PM _{2.5} ; educational level | Relative risks of non-trauma mortality were at or near significance in the group having only elementary education. |
| Filleul et al. (2003, 087403) | Residents (aged > 65) of Bordeaux, France, 1988-1997 | Days | Non-trauma mortality; BC (10th or 90th percentile levels); education level, previous occupation (domestic, skilled, intellectual) | No significant effect between BC and non-trauma mortality was observed for either SES variable. |
| Filleul et al. (2004, 087404) | Residents (aged > 65) of Bordeaux, France, 1988-1997 | Days | Non-trauma mortality, cardio-respiratory mortality; BC; educational level, previous occupation (never worked, white-collar, blue collar) | Blue collar SES group had a significant odds ratio of non-trauma mortality; high education level had a significant odds ratio for cardio-respiratory mortality. |
| Filluel et al. (2005, 087357) | Adults (aged 25-59 at enrollment) in 7 French cities, 1974-2000 | Years | Non-trauma mortality; BC, TSP; educational level | No trend as a function of education level. |
| Finkelstein et al. (2003, 056117) | Adults (aged > 40) in Hamilton-Burlington, Canada, 1992-2001 | Years | Non-trauma mortality; TSP; mean household income | Significantly higher relative risk as a function of TSP exposure for low and high income strata |
| Finkelstein et al. (2003, 056117) | Adults (aged > 40) in Hamilton-Burlington, Canada, 1992-2001 | Years | Cardio-vascular mortality; Pollution index (TSP and SO ₂) (regional, urban, near-road), traffic proximity; deprivation index | No significant relative risk as a function of pollution index or traffic proximity. |
| Gouveia & Fletcher (2000, 012132) | Residents (aged > 65) of Sao Paulo, Brazil, 1991-1993 | Days | Non-trauma mortality; PM ₁₀ ; composite SES index | Non-significant results show relative risk of non-trauma mortality as a function of PM ₁₀ slightly higher in advantaged neighborhoods. |
| Gwynn & Thurston (2001, 017206) | Residents of NY City, 1988-1990 | Days | Respiratory hospital admissions; PM ₁₀ , sulfate; race, insurance | Higher but non-significant relative risk for non-whites than whites but neither with relative risk significantly different from 1 for PM ₁₀ ; relative risk significantly higher than 1 for sulfate among non-whites. |
| Hoel et al. (2002, 042364) | Adults (aged 55-69 at enrollment) in The Netherlands, 1992-2000 | Years | Non-trauma mortality; BC (regional, urban, near-road); educational level | No significant difference in relative risk as a function of BC exposure for education level |
| Ito and Thurston (1996, 078841) | Residents of Cook County, IL, 1985-1990 | Days | Mortality; PM ₁₀ ; race, sex | Mortality increased with PM ₁₀ , effects of sex and race were noted with black females > white females > black males > white males |
| Krewski et al. (2000, 012281) | Adults (aged 25-74 at enrollment) in Six Cities cohort, 1974-1991 | Years | Non-trauma mortality, cardio-pulmonary mortality; PM _{2.5} , sulfates; educational level | Relative risk significantly greater than 1 for non-trauma mortality among those with less than high school education caused by increased PM _{2.5} and sulfate exposures |
| Krewski et al. (2000, 012281) | Adults (aged > 30 at enrollment) in American Cancer Society cohort, follow-up 1982-1989 | Years | Non-trauma mortality, cardio-pulmonary mortality; PM _{2.5} , sulfates; educational level | Relative risk significantly greater than 1 for non-trauma and cardio-pulmonary mortality as a function of PM _{2.5} exposure for less than high school and high school education; relative risk significantly greater than 1 for non-trauma and cardio-pulmonary mortality as a function of sulfate exposure for less than high school education. |
| Lee et al. (2006, 098248) | Children (aged < 15) in Seoul, Korea, 2002 | Days | Hospitalized for asthma; PM ₁₀ ; SES (listed as "high," "medium," or "low" of monitor site without explanation of criteria) | PM ₁₀ level does not vary linearly with increasing SES. Relative risk significantly greater than 1 for high and low SES. |

| Reference | Population Studied | Data interval | Metrics Used (health; pollutant; SES variable) | Study Outcome |
|--|---|---------------------------------|--|---|
| Linn et al. (1999, 011680) | Residents of South Coast Air Basin, CA, 1992-1995 | Days | Respiratory and cardiovascular hospital admissions; PM ₁₀ ; sex, ethnicity (white, black, Hispanic, other) | Impact of PM ₁₀ on cardiovascular effects increased in blacks and whites relative to Hispanics and others. |
| Martins et al. (2004, 087457) | Residents (aged > 60) of six zones of Sao Paulo, Brazil, 1997-1999 | Days | Respiratory mortality; PM ₁₀ ; % with college education, % families with monthly income > \$3500, % living in slums | % with college education and % families with monthly income > \$3500 have negative impact of effect of PM ₁₀ on respiratory mortality, % people living in slums had positive effect. |
| Norris et al. (2000, 087104) | Children (aged < 18) in Seattle, WA, 1995-1996 | Days | Emergency room visits for asthma; PM ₁₀ ; high vs. low emergency room use | Relationship between PM ₁₀ and emergency room visits not significantly impacted by overall emergency room use. |
| O'Neill et al. (O'Neill et al., 2004, 055597) | Residents (aged > 65) of Mexico City, Mexico, 1996-1998 | Days | Non-trauma mortality; PM ₁₀ and O ₃ ; % homes with electricity, % homes with piped water, % literacy, % indigenous language speakers | PM ₁₀ not associated with non-trauma mortality (but significant associations for O ₃). |
| Ou et al. (2008, 189955) | Residents (aged > 30) of Hong Kong, 1998 | Days | Non-trauma mortality; PM ₁₀ ; housing type, occupational level, education level | Housing type and blue-collar caused significantly greater impact of PM ₁₀ on mortality compared with single family housing or white-collar and never employed, respectively. |
| Pope et al. (2002, 024689) | Adults (aged > 30 at enrollment) in American Cancer Society cohort, follow-up 1982-1989 | Years | Mortality; PM _{2.5} ; education level | Non-trauma mortality increased with PM _{2.5} increase; greatest impact among those with less than high school education. |
| Romieu (2004, 093074) | Children (1 mo. – 1 yr.) in Ciudad Juarez, Mexico, 1997-2001 | Days | Total mortality, respiratory mortality; PM ₁₀ ; composite SES index | No significant association between pollutants and total mortality; significant odds ratio for respiratory mortality and PM ₁₀ for lowest SES; nearly significant association between SES and PM ₁₀ |
| Samet et al. (2000, 013132) | Residents (all ages) of 20 US cities, 1987-1994 | Days | Non-trauma mortality; PM ₁₀ (adj for O ₃ , SO ₂ , NO ₂ , CO); % high school graduates, % annual income < \$12,675, % annual income > \$100,000 | No significant association between PM ₁₀ -related non-trauma mortality and SES variables. |
| Schwartz (2000, 002470) | Residents (all ages) of 10 US cities, 1986-1993 | Days | Non-trauma mortality; PM ₁₀ ; unemployment rate, % below poverty level; % with college degree | No significant difference in the effect of poverty, college degree, or unemployment rate on the influence of PM on mortality, but unemployment rate effect slightly higher. |
| Tolbert et al. (2000, 001993) | Children (aged < 18) in Atlanta, GA, 1993-1995 | Days | Emergency room visits for asthma; PM ₁₀ ; race, Medicaid status, sex | Impact of PM ₁₀ on asthma emergency room visits was not impacted by any SES variable. |
| Villeneuve et al. (2003, 055051) | Residents (aged > 65) of Vancouver, Canada, 1986-1999 | Days | Non-trauma mortality; TSP, PM ₁₀ , and PM _{2.5} ; mean family income | Significantly higher non-trauma mortality as a function of TSP for high and low income. |
| Wheeler & Ben-Schlomo (2005, 089860) | Respondents to Health Survey of England, 1995-1997 | n/a | Decreased lung function, asthma prevalence; air quality index based on PM ₁₀ , NO ₂ , SO ₂ , benzene; social class, sex | In urban areas, lower SES significantly associated with poor air quality; in rural areas, higher SES significantly associated with poor air quality. Lower SES was shown to impact the relationship between PM ₁₀ and lung function among men but not women. |
| Wilson et al. (2007, 157149) | Residents (all ages) of Phoenix, AZ, 1995-1997 | Days; lag 0-5, 6-day moving avg | Non-trauma mortality, cardiovascular mortality; PM _{2.5} , PM ₁₀ 2.5; % < HS diploma, % below poverty level, location within city | The lower SES region of Central Phoenix had higher risk of mortality as a function of PM _{2.5} exposure. Modification of the effect of PM ₁₀ 2.5 on mortality was observed for the higher SES region. |
| Wojtyniak et al. (2001, 090372) | Residents (aged 0-70 or > 70) of Cracow, Lodz, Poznan, and Wroclaw (Poland), 1990-1996 | Days | Non-trauma and cardiovascular mortality; BC; educational level | Non-trauma and cardiovascular mortality was significantly associated with BC for those with less than secondary education. |

| Reference | Population Studied | Data interval | Metrics Used (health; pollutant; SES variable) | Study Outcome |
|--|---|---------------|--|---|
| Wong et al. (2008, 157151) | Residents of 209 tertiary planning units (smallest classification for a town), 1996-2002 | Days | Non-trauma and cardiovascular mortality; PM ₁₀ ; social deprivation index | Significant associations between PM ₁₀ and non-trauma and cardiovascular mortality for medium and high social deprivation index. |
| Zanobetti et al. (2000, 011979) | Residents of 10 US cities, 1985-1994 | Days | Respiratory and cardiovascular hospital admissions; PM ₁₀ ; % poverty, % non-white | No significant effect of SES factors on relationship between hospital admissions and PM ₁₀ . |
| Zanobetti et al. (2000, 012187) | Medicare recipients in Cook County, IL, 1985-1994 | Days | Respiratory and cardiovascular hospital admissions; PM ₁₀ ; race, sex | No significant effect of SES factors on relationship between hospital admissions and PM ₁₀ . |
| Zanobetti & Schwartz (2000, 010198) | Residents (all ages) of Chicago, Detroit, Minneapolis-St. Paul, and Pittsburgh, 1986-1993 | Days | Non-trauma mortality; PM ₁₀ (excluding days when concentrations exceeded 150 µg/m ³); education below or above high school | Higher but non-significant % increase in non-trauma mortality with 10 µg/m ³ increase in PM ₁₀ for people with less than high school education. |
| Zeka et al. (2006, 088749) | Residents (all ages) of 20 US cities, 1989-2000 | Days | Non-trauma mortality, respiratory mortality, cardiac mortality, mortality from infarction, mortality from stroke; PM ₁₀ ; educational level | No significant relationship between increased mortality (any type) with 10 µg/m ³ increase in PM ₁₀ for any SES factors. |

Some studies measured constituents other than PM; those metrics and results are not reported here.

Annex B. Dosimetry

B.1. Ultrafine Disposition

Table B-1. Ultrafine disposition in humans.

| Reference | Study Group | Aerosol | Study Protocol | Observations |
|--|--|--|---|---|
| Mills et al.(2006, 088770) | Healthy nonsmokers (5 M, 5 F; 21-24 yrs) | Carbon - 99mTc 108 nm CMD ($\sigma_g = 2.2$) Technegas Generator | Lung activity in the lung was measured at 0, 1, and 6 h post aerosol inhalation. | On avg, lung activity decreased $3.2 \pm 0.7\%$ during the first h and $1.2 \pm 1.7\%$ over the next 5 h. With 95.6% of the particles in the lungs at 6 h post inhalation and no accumulation of radioactivity detected over the liver or spleen, findings did not support rapid translocation from the lungs into systemic circulation. |
| Möller et al. (2008) | Healthy nonsmokers (n = 9; 50 ± 11 yrs) Smokers (n = 10; 51 ± 10 yrs) COPD patients (n = 7; 69 ± 10 yrs) | Carbon - 99mTc ~ 100 nm CMD Technegas Generator | On two separate occasions, subjects inhaled 100 mL aerosol boli to target front depths of 150 and 800 mL into the lungs to target the airways and alveoli, respectively. Retention measured at 10 min, 1.5, 5.5, 24 and 48 h post inhalation. Isotope (99mTc) leaching from particles assessed via filters in saline, blood, and urine. ^{81m}Kr utilized to assess ventilation. | <i>Shallow airways boli</i> – Total deposition in airways (shallow boli) similar between groups. Pattern of deposition was significantly more central in the healthy subjects which was thought due to non-uniform ventilation distribution in smokers and COPD patients as visualized by gamma-camera scans. Airway retention after 1.5 h was significantly lower in healthy subjects ($89 \pm 6\%$) than smokers ($97 \pm 3\%$) or COPD patients ($96 \pm 6\%$). At 24 and 48 h, retention significantly remained higher in COPD patients ($86 \pm 6\%$ and $82 \pm 6\%$) than healthy subjects ($75 \pm 10\%$ and $70 \pm 9\%$). <i>Deep alveolar boli</i> – Total deposition in alveoli (deep boli) significantly greater in smokers ($64 \pm 11\%$) and COPD patients ($62 \pm 5\%$) than healthy subjects ($50 \pm 8\%$). Alveolar retention of particles similar at all times between groups. For example, at 48 h, $97 \pm 3\%$ in healthy subject, $96 \pm 3\%$ in smokers, and $96 \pm 2\%$ in COPD patients. Retention at 24 and 48 correlated with isotope leaching, suggesting that the small amount of clearance primarily reflected the disassociation of 99mTc from the particles with little transport of particles from the lungs. |
| Wiebert et al. (2006, 156154) | Subjects having varied health status (9M, 6F; 46-74 yrs) 6 healthy 5 asthmatic 4 smokers | Carbon - 99mTc 87 nm CMD ($\sigma_g = 1.7$) Technegas Generator | Technegas system was modified to reduce leaching of 99mTc radiolabel from particles. The avg tidal volume during aerosol inhalation was 1.8 L (range 0.8 – 3.3). Activity in chest region measured at 0, 2, 24, 46, and 70 h after inhalation. Leaching assessed in vitro and via urine collection. | Lung function not significantly different between healthy and affected lungs. The aerosol deposition fraction was $41 \pm 10\%$. Lung retention was $99 \pm 3\%$, $99 \pm 5\%$, and $99 \pm 10\%$ at 24, 46, and 70 h post inhalation. Cumulative in vitro leaching by 70 h was $2.6 \pm 0.96\%$. Except for radiotracer leaching from particles ($1.0 \pm 0.6\%$ of initially deposited activity in urine by 24 h), there was not significant clearance from the lungs by 70 h. Individual leaching was not correlated with individual retention. |

Note: Hyperlinks to the reference citations throughout this document will take you to the NCEA HERO database (Health and Environmental Research Online) at <http://epa.gov/hero>. HERO is a database of scientific literature used by U.S. EPA in the process of developing science assessments such as the Integrated Science Assessments (ISA) and the Integrated Risk Information System (IRIS).

| Reference | Study Group | Aerosol | Study Protocol | Observations |
|---|--|---|---|---|
| Wiebert et al. (2006, 1597146) | Healthy subjects (4M, 5F; 56 ± 9 yrs) Asthmatics (2M, 3F; 59 ± 6 yrs) Control (1M; 50 yrs) | Carbon - 99mTc 34 nm CMD ($\sigma_g = 1.5$) Technegas Generator | Slow deep aerosol inhalations with 10s breath hold. Mean inhalation time of 6 min. Control subject inhaled aerosol with loosely bound radiolabel. Retention scans at 10 min, 60 min, 100 min, and 24 h post inhalation. Leaching assessed in vitro and via collection of blood and urine. | Avg deposition fraction of $60 \pm 17\%$ which was correlated with tidal volume during aerosol inhalation ($p = 0.01$). Activity excreted in urine over 24-h post inhalation was 51% in the control subject (high 99mTc disassociation) and $3.6 \pm 0.9\%$ of deposited activity. In the blood of the control subject, activity was 30%, 31%, and 5% of the deposited activity at 20 min, 80 min, and 24-h (respectively), whereas it was only $0.9 \pm 0.6\%$, $1.1 \pm 0.4\%$, and $1.5 \pm 0.5\%$ the other 13 subjects at these times. Lung retention in the control subject was 30% at 1-h and 18% at 24 h. In the remainder of subjects, lung retention was approximately 100% through 24 h. |

Table B- 2. Ultrafine disposition in animals.

| Reference | Study Group | Aerosol | Study Protocol | Observations |
|---|--|--|--|---|
| Bermudez et al. (2004, 189730) | Fischer 344 rats, females (6 wks) B3C3F1 mice, females (6 wks) Hamsters, females (6 wks) | TiO ₂ : 1.29–1.44 μm MMAD ($\sigma_g = 2.46$ -3.65), 21 nm primary particles | Animals exposed 6 h/day, 5 day/wk, for 13 weeks to 0.5, 2 and 10 mg/m ³ . Control animals exposed to filtered air. Animals sacrificed at 0, 4, 13, 26, and 56 (49 for hamsters) postexposure. Groups of 25 animals per species and time point. | TiO ₂ pulmonary retention half-times for the low-, mid-, and high-exposure groups, respectively: 63, 132, and 365 days in rats; 48, 40, and 319 days in mice; and 33, 37, and 39 days in hamsters. Burden of TiO ₂ in lymph nodes increase with time postexposure in mid- and high-dosed rats; in high-dosed mice; but was unaffected in hamsters at any time or dosage group. In high-exposure groups of mice, epithelial permeability remained elevated ($\sim 2 \times$ control groups) out to 52 weeks without signs of recovery. Epithelial permeability was $3\text{-}4 \times$ control in high exposed rats through 4 weeks post exposure, but approached control by 13 weeks. Epithelial permeability was unaffected in all groups of hamsters. |
| Chen et al. (2006, 087362) | Sprague-Dawley male rats (220 ± 20 g) | Polystyrene 125I radiolabel Ultrafine: 56.4 nm Fine: 202 nm | Intratracheal instillation of particles in healthy rats or those pretreated with LPS (12 h before particle instillation). Healthy rats sacrificed between 0.5-2 h and at 24 or 48 h post-instillation. LPS treated rats were sacrificed 0.5-2 h post-instillation. | In healthy rats, there were no marked differences in lung retention or systemic distribution between the ultrafine and fine particles. Results for healthy animals focused on ultrafine particles which were primarily retained in lungs ($72 \pm 10\%$ at 0.5-2 h; $65 \pm 1\%$ at 1 day; $62 \pm 5\%$ at 5 days). Initially, there was rapid particle movement into the blood ($2 \pm 1\%$ at 0.5-2 h; $0.1 \pm 0.1\%$ at 5 days) and liver ($3 \pm 2\%$ at 0.5-2 h; $1 \pm 0.1\%$ at 5 days). At 1 day post-instillation, about 13% of the particles where in the urine or feces. Following LPS treatment, ultrafine accessed the blood (5 vs. 2%) and liver (11 vs. 4%) to a significantly greater extent than fine particles. |
| Geiser et al. (2005, 087362) Also included in vitro study | Wistar rats 20 adult males (250 ± 10 g) | TiO ₂ (22 nm CMD, 1.7 σ_g) Spark generated 0.11 mg/m ³ 7.3×10^6 particles/cm ³ | Rats exposed 1-h via endotracheal tube while anesthetized and ventilated at constant rate. Lungs fixed at 1 or 24-h postexposure. | Distributions of particles among lung compartments followed the volume distribution of compartments and did not differ significantly between 1 and 24-h post-inhalation. On avg, $79.3 \pm 7.6\%$ of particles were on the luminal side of the airway surfaces, $4.6 \pm 2.6\%$ in epithelial or endothelial cells, $4.8 \pm 4.5\%$ in connective tissues, and $11.3 \pm 3.9\%$ within capillaries. Particles within cells were not membrane-bound. |
| Kapp et al. (2004, 156624) | Charles River rats 5 young adult male (250 ± 10 g) | TiO ₂ (22 nm CMD, 1.7 σ_g) Spark generated | --Rats exposed 1-h via endotracheal tube while anesthetized and ventilated at constant rate. Lungs fixed immediately postexposure. | Of particles in tissues, 72% were aggregates of 2 or more particles; 93% of aggregates were in round or oval shape aggregates, 7% were needle-like. The size distribution of particles in lung tissues (29 nm CMD, 1.7 σ_g) was remarkably similar to the aerosol; the small discrepancy may have been due to differences sizing techniques. A large 350 nm aggregate was found in a type II pneumocyte, a 37 nm particle in a capillary close to the endothelial cells, and a 106 nm particle within the surface-lining layer close to the alveolar epithelium. |

Table B- 3. In vitro studies of ultrafine disposition.

| Reference | Animal | Particles | Study Protocol | Observations |
|--|---|---|---|--|
| Edetsberger et al. (2005, 155759) | Human cervix carcinoma cells (HeLa cells) | Polystyrene spheres (0.020 µm) | Cells incubated with polystyrene particles having negative surface charges. Cell cultures were naïve or treated with Genistein or Cytochalasin B (CytB) prior to particle application. Genistein inhibits endocytotic processes, especially caveolae internalization. CytB inhibits actin polymerization and phagocytosis. | Particles translocated into cells by first measurement (~ 1 min after particle application) independent of treatment group. In naïve cells, agglomerates of 88-117 nm were seen by 15-20 minutes and of 253-675 nm by 50-60 minutes after particle application. Intracellular aggregates thought to be result from particle incorporation into endosomes or similar structures. In treated cells, only a small number of agglomerates (161-308 nm) were found and only by 50-60 minutes. At 50-60 minutes, 90% and 98% of particles were in the 20-40 nm range in naïve and treated cells, respectively. Particles did not translocate into dead cells, rather they attached to outside of the cell membrane. |
| Geiser et al. (2005, 087362) <i>Also included inhalation study</i> | Porcine lung macrophages (10 ⁶ cell/mL human red blood cells (RBC; 8 × 10 ⁶ cells/mL) | Fluorescent polystyrene spheres (0.078, 0.2, and 1 µm) Gold spheres (0.025 µm) | Cells cultured for 4 h with each sized polystyrene spheres. RBC were employed as a model of nonphagocytic cells. Some macrophages cultures were treated with cytochalasin D (cytD) to inhibit phagocytosis. In addition, RBC were also cultured with gold particles. | Of the non-cytD treated macrophages, 77 ± 15%, 21 ± 11%, and 56 ± 30% contained 0.078, 0.2, and 1 µm particles, respectively. CytD treatment of macrophages effectively blocked the phagocytosis of 1 µm particles, but did not alter the uptake of the 0.078 and 0.2 µm particles. Human RBC were found to contain 0.078 and 0.2 µm polystyrene spheres as well as the 0.025 µm gold particles, which were not membrane bound. In contrast, the RBC did not contain the larger 1 µm polystyrene spheres. Results suggest that ultrafine and fine (0.078 and 0.2 µm diameter) particles cross cellular membranes by a non-endocytic (i.e. not involving vesicle formation) mechanisms such as adhesive interactions and diffusion. |
| Geys et al. (2006, 155789) | Human alveolar (A549) and bronchial (Calu-3) epithelial cells Rat primary type II pneumocytes | Amine- and carboxyl-modified fluorescent polystyrene (46 nm) | Cells cultured in clear polyester transwells with 0.4 or 3 µm pores. Monolayer considered "tight" when < 1% sodium fluorescein moved from apical to basolateral compartment. Particle translocation assessed in transwells with and without cells. Cells incubated with particles for 14-16 h to assess translocation from apical to basolateral compartment. | Without cells, 13.5% of carboxyl-modified particles passed through the 0.4 µm pores (n = 7) and 67.5% through 3 µm pores (n = 3). Movement of the amine-modified particles was 4.2% through 0.4 µm pores (n = 7) and 52.7% through 3 µm pores (n = 3). The integrity of the monolayer was insufficient for translocation studies using the A549 cells (0.4 and 4 µm pore size) and rat pneumocytes (0.3 µm pore). Using 0.4 µm pores, there was no detectable translocation through either Calu-3 or rat pneumocyte monolayers. Using 3 µm pores, ~ 6% of both particle types passed through the Calu-3 monolayer; however, results were highly variable with no translocation in 2 (of 5) and 3 (of 6) trials with carboxyl- or amine-modified particles, respectively. |

B.2. Olfactory Translocation

Table B-4. Olfactory particle translocation.

| Reference | Study Group | Aerosol | Study Protocol | Observations |
|--|---|--|---|--|
| DeLorenzo (1970, 156391) | Squirrel monkeys young males (1 kg) | Silver-coated colloidal gold (50 nm) | Intranasal instillation of 1 mL particle suspension. Animals sacrificed at 0.25, 0.5, 1, and 24-h after instillation. | Rapid movement (30-60 min) into olfactory bulbs. Within 30 min of being placed on nasal mucosa, particle aggregates were seen in axoplasm of the fila olfactoria. Within 1 h, particles were in olfactory glomerulus. Particles in the olfactory bulb were located preferentially in mitochondria and not free in the cytoplasm. |
| Dorman et al. (2001, 055433) | Ctrl: CD rats Males (6 wks old) | Soluble and insoluble Mn particle types; MMAD = 1.3-2.1 μm ; GSD < 2 | Whole body exposure (6 h/day, 14 consecutive days) to 0, 0.03, 0.3, and 3 mg Mn/m ³ . Tissues analyzed in six animals per concentration exposed to soluble (MnSO ₄) or insoluble (Mn ₃ O ₄) aerosols. | Increased Mn levels in olfactory bulb observed following MnSO ₄ of ≥ 0.3 mg Mn/m ³ and following Mn ₃ O ₄ of 3 mg Mn/m ³ . At 3 mg Mn/m ³ , Mn levels were significantly greater in olfactory bulb (1.4-fold) and striatum (2.7-fold) following soluble MnO ₄ than insoluble Mn ₃ O ₄ . Mn levels in the cerebellum were unaffected following all exposures. |
| Dorman et al. (2004, 155752) | Ctrl: CD rats Males (6 wks old) | Soluble and insoluble Mn particle types; MMAD = 1.5-2 μm ; GSD = 1.4-1.6 | Whole body exposure (6 h/day, 5 days/wk, 13 wks) to MnSO ₄ at 0, 0.01, 0.1, and 0.5 mg Mn/m ³ . Compared to Mn phosphate (as hureaulite) exposure of 0.1 mg Mn/m ³ . Brain Mn levels assessed immediately following 90 days of exposure or 45 days postexposure. | Relative to air, the insoluble hureaulite was significantly increased at 90 days of exposure in the olfactory bulb, but not striatum or cerebellum. The soluble Mn phosphate showed a dose dependent increase in olfactory bulb Mn levels at 90 days. At 0.1 mg Mn/m ³ , Mn levels following Mn phosphate were significantly increased in the olfactory bulb and striatum relative to hureaulite and air exposures. At 45 days postexposure, relative to air, olfactory bulb Mn levels only remained increased Mn phosphate group at 0.5 mg Mn/m ³ . |
| Elder et al. (2006, 089253) | Fisher 344 rats Males (200-250 g) | Mn oxide (~30 nm equivalent sphere with 3-8 nm primary particles) Spark generated 0.5 mg/m ³ 18 \times 10 ⁶ particles/cm ³ | Whole body inhalation exposure to either filtered air or Mn oxide for 12 days (6 h/day, 5 days/wk) with both nares open or Mn oxide for 2 days (6 h/day) with right nostril blocked. Intranasal instillation in left nostril of Mn oxide particles or soluble MnCl ₂ suspended in 30 μL saline. Analyzed Mn in the lung, liver, olfactory bulb, and other brain regions. | After 12 day exposure via both nostrils, Mn in the olfactory bulb increased 3.5-fold, whereas in the lung Mn concentrations doubled; there were also increases in the striatum, frontal cortex, and cerebellum. After the 2 days exposure with the right nostril blocked, Mn accumulated in the mainly in the left olfactory bulb (~2.4-fold increase) in to a lesser extent in the right olfactory bulb (1.2-fold increase). At 24-h post instillation, the left olfactory bulb contained similar amounts of the poorly soluble Mn oxide (8.2 \pm 0.7%) and soluble MnCl ₂ (8.2 \pm 3.6%) as a percent of the amount instilled. |
| Oberdörster et al. (2004, 055639) | Fisher 344 rats Males (14 wks; 284 \pm 9 g) | ¹³ C (36 nm CMD, 1.7 σ) Spark generated | Rats (n = 12, 3 per time point) exposed to 160 $\mu\text{g}/\text{m}^3$ for 6 h in whole-body chamber and sacrificed at 1, 3, 5, and 7 day postexposure. Lung, olfactory bulb, cerebrum, and cerebellum removed for ¹³ C analysis. Tissue ¹³ C-levels were determined by isotope ratio mass spectroscopy and background corrected for ¹³ C levels in unexposed controls (n = 3). | At 1 day postexposure, the lungs of rats exposed to ultrafine ¹³ C particles contained 1.34 \pm 0.22 μg of ¹³ C (1.39 $\mu\text{g}/\text{g}$ -lung) following background corrected. By 7 days postexposure, the ¹³ C concentration had decreased to 0.59 $\mu\text{g}/\text{g}$ -lung. There was a significant and persistent increase in ¹³ C in the olfactory bulb of 0.35 $\mu\text{g}/\text{g}$ on day 1, which increased to 0.43 $\mu\text{g}/\text{g}$ by day 7. Day 1 concentrations of ¹³ C in the cerebrum and cerebellum were also significantly increased but the increase was inconsistent, possibly reflecting translocation of particles from the blood across the blood-brain barrier into brain regions. |
| Persson et al. (2003, 051846) | Sprague-Dawley male rats (150 g) Freshwater Pike female (3 kg) | ⁶⁵ ZnCl ₂ dissolved in 0.1 M HCl | Rats: intranasal (0.03 μg Zn in 10 μL) or intraperitoneally (0.03 μg Zn in 100 μL); autoradiography and γ spec at 1 day or 1, 3, or 6 weeks postexposure. Pike: instilled (0.12 μg Zn in 10 μL) in right or both olfactory chambers, assayed 2 weeks postexposure | Zn uptake in olfactory epithelium and transport along olfactory neurons to olfactory bulb. Zn continued into interior of olfactory bulb and in rat went into anterior olfactory cortex. Zn found bound to both cellular constituents and cytosolic components. Some Zn bound to metallothionein in olfactory mucosa and olfactory bulb. |

| Reference | Study Group | Aerosol | Study Protocol | Observations |
|---|--|--|---|---|
| Wang et al. (2007, 156147) | CD-1 (ICR) mice | Rutile TiO ₂ 21 and 80 nm Anatase TiO ₂ 155 nm | Twenty mice (n = 5 per group) exposed 0 or 0.01 g-TiO ₂ per mL DI. Instilled 25 μ L each day for 5 days, then inhaled 10 μ L every other day. Mice sacrificed after one month. | Rutile particles were observed to be column/fiber shaped, whereas anatase was octahedral. TiO ₂ particles taken up by olfactory bulb via the olfactory nerve layer, olfactory ventricle, and granular cell layer of the olfactory bulb. Fine TiO ₂ showed greater entry into the olfactory bulb presumably due to aggregation of smaller rutile particles that was not seen for the fine anatase particles. |
| Yu et al. (2003, 156171) | Sprague-Dawley male rats, 6 wks old (218 \pm 10 g) | Stainless steel welding-fume < 0.5 μ m | Whole body exposure 2 h/day for 1, 15, 30, or 60 days Low: 64 \pm 4 mg/m ³ (1.6 mg/m ³ Mn) High: 107 \pm 6 mg/m ³ (3.5 mg/m ³ Mn) | Significant increases in cerebellum Mn at 15 – 30 days of exposure. Slight increases in Mn in substantia nigra, basal ganglia, temporal cortex, and frontal cortex after 60 days. Significant increase at 30 days in basal ganglia at low dose. Authors suggested that pharmacokinetics and distribution of welding fume Mn differs from pure Mn. |

B.3. Clearance and Age

Table B-5. Studies of respiratory tract mucosal and macrophage clearance as a function.

| Reference | Animal | Particles | Study Protocol | Observed Effect(s) |
|--|--------------------------------|---|---|---|
| <i>NASAL AND TRACHEAL CLEARANCE</i> | | | | |
| Ho et al. (2001, 156549) | Human, males and females | Not applicable | Ninety subjects (47 M, 43 F; 52 \pm 23 yrs) between 11 and 90 years of age were recruited to measure nasal saccharine clearance and ciliary beat frequency. | Ciliary beat frequency (n = 90; r = -0.48, p < 0.0001) and nasal mucociliary clearance time (n = 43; r = 0.64, p < 0.001) were correlated with subject age. Nasal clearance times were significantly (p < 0.001) faster in individuals under 40 years of age (9.3 \pm 5.2 min) versus older subjects (15.4 \pm 5.0 minutes). Results similar between males and females. |
| Goodman et al. (1978, 071130) | Humans, males and females | Radiolabeled Teflon disks (1 mm diameter, 0.8 mm thick) | Tracheal mucus velocity following delivery via bronchoscope to the tracheal mucosa. Ten young (2 M, 8 F; 23 \pm 3 yrs) and ten elderly (2 M, 5 F; 63 \pm 5 yrs) nonsmokers served as control subjects. Measurements were also made in young smokers, ex-smokers, and individuals with chronic bronchitis. | Young nonsmokers had a tracheal mucus velocity of 10.1 \pm 3.5 mm/min which was significantly faster than the velocity of 5.8 \pm 2.6 observed in the elderly nonsmokers. |
| Whaley et al. (1987, 156153) | Beagle dogs, males and females | Macroaggregated albumin ^{99m} Tc labelled | Intratracheal instillation of 10- μ L droplet of labelled albumin in saline. Tracheal clearance followed 25 minutes. Longitudinal measure measurements in 5 males and 3 females when young adults (2.8-3 yr), middle-aged (6.7-6.9 yr), and mature (9.6-9.8 yr). Additional 5 females and 3 males comprised immature group (9-10 mo) and 4 males and 4 females used as aged group (13-16 yr). | Tracheal mucus velocity significantly (p < 0.05) greater in young (9.7 \pm 0.6 [SE] mm/min) and middle-aged (6.9 \pm 0.5) groups than in immature (3.6 \pm 0.4), mature (3.5 \pm 0.8), and aged (2.9 \pm 0.5) dogs. |

| Reference | Animal | Particles | Study Protocol | Observed Effect(s) |
|---|---------------------------|------------------------------|--|---|
| Yeates et al. (1981, 095391) | Humans, males and females | Radioaerosols 99mTc labelled | Tracheal mucus velocities compiled for 74 healthy non-smoking subjects (60 M, 14 F; 10-65 yrs, mean 30 yrs) from prior studies. Forty-two (32 M, 10 F) inhaled albumin in saline droplets (6.2-6.5 μ m MMAD), Yeates et al. (1975); twenty-two (21 M, 1 F) inhaled iron oxide (4.2 μ m MMAD), Yeates et al. (1981b); and ten (7 M, 3 F) inhaled monodisperse iron oxide aerosol (7.5 μ m MMAD), Leikauf et al. (1981). Inhalations were via a mouthpiece with an inspiratory flow of \sim 1 liter/sec. | A lognormal distribution of tracheal mucus velocities was reported. Age did not appear to affect velocities, e.g., 4.7 ± 2.5 mm/min in 18-24 yrs olds vs. 4.6 ± 3.2 mm/min in individuals > 30 yrs of age. However, it should be noted that only 2 subjects were greater than 45 yrs of age and that the data was compiled from three studies using differing experimental techniques. Rather similar tracheal mucus velocities in males (4.7 ± 3.0 mm/min) and females (4.9 ± 2.4 mm/min). |

BRONCHI AND BRONCHIOLES CLEARANCE

| | | | | |
|--|---------------------------|--|---|--|
| Puchelle et al. (1979, 006863) | Human, males | 7.4 μ m MMAD99mTc labelled resin | Mucociliary clearance measured for 1 h post aerosol inhalation in 19 healthy non-smoking males (21-69 yrs of age). Clearance measure on two occasions in 16 individuals. | Negative correlation ($r = -0.472, p < 0.05$) between mucociliary clearance and age. Younger subjects ($n = 9$; 21-37 yrs) had 1-h clearance of $34 \pm 14\%$ which was significantly greater than the $22 \pm 8\%$ found in the older subjects ($n = 5$; > 54 yrs). Separated by 5.4 wks (on avg), there was a good correlation between repeated clearance measurements ($r = 0.65, p < 0.001$) |
| Svartengren et al. (2005, 157034) | Humans, males and females | 6 μ m MMAD111In labelled Teflon | Small airway clearance measured in five age groups (\square 24 yrs, $n = 13$; 25-29 yrs, $n = 8$; 30-49 yrs, $n = 7$; 50-64, $n = 9$; > 65 yrs, $n = 9$) of healthy subjects. Aerosol inhaled via mouthpiece at extremely slow rate of 0.05 L/s. Activity in lungs measured at 1 day, 2 days, and 1, 2, and 3 wks post-exposure. Under the presumption that most large airway clearance was complete by 24 h, retention at 24 h was normalized to 100%. | Large and small airway clearance slowed with increasing age. Clearance correlated with age at all times ($r = -0.46$ to $-0.50, -0.55, -0.66$, and -0.70 at 1 day, 2 days, 1 wk, 2 wks, and 3 wks, respectively). Based on linear regression, the clearance from 1 to 21 days post-exposure was 47% in a 20 yr-old versus 23% in an 80 yr-old. Lung function was not a significant predictor of clearance when age considered. |
| Vastag et al. (1985, 157088) | Humans, males and females | Monodisperseerythrocytes99mTc labelled | Clearance measured for 1-h post-inhalation in eighty healthy (59 M, 21 F; 43 ± 17 yrs) subjects who had never smoked. Smokers and ex-smokers also studied. Aerosol inhalation not described. | Clearance significantly associated with age. Based on linear regression, total mucociliary clearance at 1-h post-exposure was 46% in a 20-yr-old versus 23% in an 80 yr-old. Similar results for males and females. |

ALVEOLAR CLEARANCE

| | | | | |
|--|------------------|--|---|--|
| Muhle et al. (1990, 006853) | Fischer 344 rats | 3.5 μ m MMAD 85Sr labelled polystyrene latex | Control animals compared across several studies. Aerosol inhaled by short-term nose only exposure. Alveolar clearance determined by exponential fit to thoracic activity measured over 75-100 days excluding the first 15 days post-exposure. | Typical alveolar clearance half-time of 45 days in 5-month-old rats compared to 74 days in 23-month-old rats. Statistical significance of findings not proved. |
|--|------------------|--|---|--|

Annex C. Controlled Human Exposure Studies

Table C-1. Cardiovascular Effects

| Study | Pollutant | Exposure | Findings |
|--|---|---|---|
| Reference: Barregard et al. (2006, 091381) Subjects: 13 healthy adults Gender: 6 M/ 7 F Age: 20-56 yrs | Pollutant: Wood smoke Particle Size: Session 1: GMD 42 nm; Session 2: GMD 112 nm Particle Number/Count: Session 1: 180,000/cm ³ ; Session 2: 95,000/cm ³ Concentration: Session 1: median: 279 µg/m ³ ; Session 2: median 243 µg/m ³ | Subjects exposed in two groups for 4 h to filtered air, followed a wk later by a 4-h exposure to wood smoke. Exposures conducted with two 25-min periods of light exercise. Other measured combustion products: Session 1: NO ₂ (0.08 ppm), CO (13 ppm), formaldehyde (114 µg/m ³), acetaldehyde (75 µg/m ³), benzene (30 µg/m ³), 1,3-butadiene (6.3 µg/m ³); Session 2: NO ₂ (0.09 ppm), CO (9.1 ppm), formaldehyde (64 µg/m ³), acetaldehyde (40 µg/m ³), benzene (20 µg/m ³), 1,3-butadiene (3.9 µg/m ³). Time to analysis: Immediately following exposure as well as 3 and 20 h post-exposure. | Statistically significant increase in plasma factor VIII 20 h post wood smoke exposure relative to filtered air. The factor VIII/von Willebrand ratio in plasma was increased with wood smoke relative to filtered air at 0, 3, and 20 h post-exposure. Wood smoke exposure increased the urinary excretion of free 8-iso-prostaglandin _{2α} relative to clean air 20 h post-exposure (n = 9). These findings were more pronounced in session 1 than session 2 (similar mass concentration but higher number concentration in session 1). |
| Reference: Beckett et al. (2005, 156281) Subjects: 12 healthy adults Gender: 6 M/6 F Age: 23-52 yrs | Pollutant: Ultrafine and fine zinc oxide Particle Size: UF: < 0.1 µm; Fine: 0.1-1.0 µm Particle Number/Count: UF: 4.6 × 10 ⁷ /cm ³ ; Fine: 1.9 × 10 ⁵ /cm ³ Concentration: 500 µg/m ³ | Subjects exposed via mouthpiece for 2 h during rest to filtered air, ultrafine, and fine zinc oxide in a randomized crossover study design. Exposures were separated by at least 3 wks. Time to analysis: Immediately following exposure and 3, 6, 11, 23, and 24 h after exposure. | Exposure to ultrafine and fine zinc oxide did not affect HRV (time and frequency domain parameters) relative to clean air immediately following exposure, or at 3, 6, 11, and 23 h post-exposure. Exposure did not affect blood pressure through 24 h post-exposure. No effects of exposure to either fine or ultrafine zinc oxide observed on factor VII, von Willebrand factor (vWf), tissue plasminogen activator (t-PA), or fibrinogen. No effect of exposure observed on peripheral blood cell counts or levels of pro-inflammatory cytokines. |
| Reference: Blomberg et al. (2005, 191991) Subjects: 15 older adults (former smokers) with COPD Age: 56-72 yrs | Pollutant: DE Concentration: 300 µg/m ³ | Subjects exposed for 1 h with intermittent exercise to DE and filtered air in a randomized crossover study design. Time to analysis: 6 and 24 h post-exposure. | DE was not observed to affect blood levels of C-reactive protein, fibrinogen, D-Dimer, prothrombin factor 1-2, or von Willebrand factor activity at 6 and 24 h post-exposure. |

| Study | Pollutant | Exposure | Findings |
|--|--|--|--|
| Reference: Brauner et al. (2007, 188507) Subjects: 29 healthy adults Gender: 20 M/9 F Age: 20-40 yrs | Urban traffic particles Particle Number/Count: 6-700nm: 10,067/cm ³ Concentration: PM _{2.5} : 9.7 µg/m ³ ; PM _{2.5-10} : 12.6 µg/m ³ | Subjects exposed to urban traffic particles and filtered air for 24 h with and without two 90-min periods of light exercise in a randomized crossover study design. Concentrations of NO _x and NO were low and did not differ between filtered and unfiltered exposures. CO concentrations were higher with filtered air (0.35 and 0.41 ppm), while ozone concentrations were lower with filtered air (12.08 and 4.29 ppb). Time to analysis: 6 and 24 h after the start of exposure. | An increase in DNA strand breaks and formamidopyrimidine-DNA glycosylase sites in peripheral blood mononuclear cells were observed after 6 and 24 h of exposure to urban particulates. The particle concentration at the 57nm mode was shown to be the major contributor to these effects. |
| Reference: Brauner et al. (2008, 156293) Subjects: 42 healthy older adults (21 couples) Age: 60-75 yrs | Indoor air particles Particle Number/Count: 10-700 nm: 10,016/cm ³ Concentration: Coarse: 9.4 µg/m ³ ; Fine: 12.6 µg/m ³ | Exposures consisted of two 48 h periods in the home of each subject with or without the use of a HEPA filter (randomized crossover design). HEPA filters reduced coarse concentration from 9.4 to 4.6 µg/m ³ , and fine concentration from 12.6 to 4.7 µg/m ³ . Concentrations of NO ₂ did not differ between the 2 sessions (20 ppb). Time to analysis: After the completion of each 48 h session. | The use of HEPA filters significantly improved microvascular function (p = 0.04) after 48 h (reactive hyperemia-peripheral arterial tonometry). Microvascular function was assessed using a scoring system representing the extent of reactive hyperemia. The reduction in PM concentration through the use of HEPA filters did not significantly affect blood pressure following the 48-h exposures. Lowering PM concentration did not significantly affect inflammatory response markers in peripheral venous blood (IL-6, TNF-α, C-reactive protein, plasma amyloid A). |
| Reference: Brauner et al. (2008, 191966) Subjects: 29 healthy adults Gender: 20 M, 9 F Age: M avg 27 yrs, F avg 26 yrs | Urban traffic particles Particle Number/Count: 6-700 nm: 10,067/cm ³ Concentration: PM _{2.5} : 9.7 µg/m ³ ; PM _{2.5-10} : 12.6 µg/m ³ | Subjects exposed to urban traffic particles and filtered air for 24 h with and without two 90-min periods of light exercise in a randomized crossover study design. Concentrations of NO _x and NO were low and did not differ between filtered and unfiltered exposures. CO concentrations were higher with filtered air (0.35 and 0.41 ppm), while ozone concentrations were lower with filtered air (12.08 and 4.29 ppb). Time to analysis: 6 and 24 h after the start of exposure. | Exposure to urban traffic particles was not observed to affect microvascular function (digital peripheral artery tone) at 6 or 24 h after the start of exposure. No difference in various blood markers of coagulation, inflammation, or protein oxidation (e.g., fibrinogen, platelet count, CRP, IL-6, TNF-α) were demonstrated between particle and filtered air exposure. |
| Reference: Carlsen et al. (2007, 155714) Subjects: 13 healthy adults Gender: 11 M/2 F Age: 20-42 yrs | DE 2002 Cummins B-series diesel engine (6BT5.9G6, 5.9 L) operating at load Concentration: Fine PM: 100, 200 µg/m ³ | Subjects exposed for 2 h at rest to filtered air and each of the two DEPs concentrations in a randomized crossover study design. Exposures were separated by at least 2 wks. Other diesel emissions measured: NO ₂ (10-35 ppb), CO (0.7-1.8 ppm). Time to analysis: 3, 6, and 22 h after the start of exposure. | No statistically significant changes in plasminogen activator inhibitor-1 (PAI-1), vWf, D-dimer, or platelet count observed 3, 6, or 22 h following exposure to DE relative to filtered air. Non-statistically significant increases in D-dimer, vWf, and platelet count was observed at 6 h following the start of exposure (4 h post-exposure). No diesel-induced increase in C-reactive protein observed in relative to filtered air in peripheral venous blood at 1 or 20 h post-exposure. |
| Reference: Carlsen et al. (2008, 156323) Subjects: 16 adults with metabolic syndrome Gender: 10 M/6 F Age: 25-48 yrs | DE 2002 Cummins B-series diesel engine (6BT5.9G6, 5.9 L) Concentration: Fine PM: 100, 200 µg/m ³ | Subjects exposed for 2 h at rest to filtered air and each of the two DE particle concentrations in a randomized crossover study design. Exposures were separated by at least 2 wks. Other diesel emissions measured: NO ₂ (30 ppb), NO (1.69 ppm), CO (0.65 ppm). Time to analysis: 3, 7, and 22 h after the start of exposure. | At 5 h after the end of diesel exposure (fine particulate concentration 200 µg/m ³), the authors observed a significant decrease in vWf in peripheral venous blood. No other changes in thrombotic markers (vWf, D-dimer, PAI-1) were observed at either concentration between 1 and 20 h post-exposure. |

| Study | Pollutant | Exposure | Findings |
|---|---|---|--|
| Reference: Danielsen et al. (2008, 156382) Subjects: 13 healthy adults Gender: 6 M/ 7 F Age: 20-56 yrs | Wood smoke Particle Size: Session 1: GMD 42 nm; Session 2: GMD 112 nm Particle Number/Count: Session 1: 180,000/cm ³ ; Session 2: 95,000/cm ³ Concentration: Session 1: median: 279 µg/m ³ ; Session 2: median 243 µg/m ³ | Subjects exposed in two groups for 4 h to filtered air, followed a wk later by a 4-h exposure to wood smoke. Exposures conducted with two 25-min periods of light exercise. Other measured combustion products: Session 1: NO ₂ (0.08 ppm), CO (13 ppm), formaldehyde (114 µg/m ³), acetaldehyde (75 µg/m ³), benzene (30 µg/m ³), 1,3-butadiene (6.3 µg/m ³); Session 2: NO ₂ (0.09 ppm), CO (9.1 ppm), formaldehyde (64 µg/m ³), acetaldehyde (40 µg/m ³), benzene (20 µg/m ³), 1,3-butadiene (3.9 µg/m ³). Time to analysis: 3 and 20 h post-exposure. | Exposure to wood smoke increased the mRNA levels of <i>hOGG1</i> in PBMCs relative to filtered air 20 h after exposure. DNA strand breaks were shown to decrease in PBMCs 20 h after wood smoke exposure. |
| Reference: Devlin et al. (2003, 087348) Subjects: 10 healthy older adults Gender: 7 M/ 3 F Age: Avg 66.9 yrs | Fine CAPs (Chapel Hill, NC) Concentration: Mean: 40.5 µg/m ³ , Range: 21.2-80.3 µg/m ³ | Exposures conducted for 2 h at rest to filtered air and CAPs in a randomized crossover study design. Time to analysis: Immediately following exposure and 24 h post-exposure. | CAPs exposure resulted in statistically significant reductions (p < 0.05) in time domain (PNN50) and frequency domain (HF power) parameters relative to clean air immediately following exposure. These relative decreases were still apparent 24 h after exposure (p < 0.08). |
| Reference: Fakhri et al. (2009, 191914) Subjects: 50 adults (40 healthy, 10 asthmatic) Gender: 24 M/26 F Age: 19-48 yrs | Fine CAPs (Toronto) Concentration: 127 ± 62 µg/m ³ with and without co-exposure to ozone (114 ± ppb) | Exposures conducted through a facemask which covered the subject's nose and mouth. Subjects were exposed to CAPs, ozone, CAPs + ozone and filtered air for 2 h at rest in a randomized crossover study design. Time to analysis: Every 30 min during exposure, with the final measurement made immediately prior to the end of the exposure. | Exposure to CAPs or ozone, alone or in combination, resulted in no significant changes in HRV or blood pressure relative to filtered air. However, a negative concentration response relationship was reported between CAPs concentration with co-exposure to ozone and SDNN, rMSSD, HF power and LF power (statistically significant for LF power). Diastolic blood pressure was observed to increase with exposure to CAPs + ozone, but not with either pollutant alone. There was no difference in response between asthmatics and healthy subjects. |
| Reference: Frampton et al. (2006, 088665) Subjects: 16 asthmatic adults, 40 healthy adults Gender: Asthmatics: 8 M/8 F, Healthy: 20 M/20 F Age: 18-40 yrs | Ultrafine elemental carbon Particle Size: CMD ~ 25 nm Particle Number/Count: 10 µg/m ³ : ~ 2.0 × 10 ⁹ /cm ³ ; 25 µg/m ³ : ~ 7.0 × 10 ⁹ /cm ³ ; 50 µg/m ³ : ~ 10.8 × 10 ⁹ /cm ³ Concentration: 10, 25, and 50 µg/m ³ | Study conducted using a randomized crossover design with 2-h exposures. Asthmatics (n = 16) exposed to filtered air and 10 µg/m ³ . 12 healthy adults exposed to filtered air and 10 µg/m ³ at rest; 12 healthy adults exposed to filtered air, 10 and 25 µg/m ³ with intermittent exercise; 16 healthy adults exposed to filtered air and 50 µg/m ³ with intermittent exercise. Exposures were conducted via mouthpiece. Time to analysis: Immediately following exposure as well as 3.5, 21, and 45 h post-exposure. | No effect of ultrafine particle exposure on leukocyte counts or leukocyte expression of adhesion molecules observed in healthy subjects exposed at rest to 10 µg/m ³ . Among healthy adults exposed to ultrafine carbon during exercise, monocyte expression of adhesion molecules CD54 and CD18 decreased relative to filtered air immediately following exposure. An ultrafine particle-induced decrease in PMN expression of CD18 was also observed 0-21 h post-exposure. Expression of CD11b on monocytes and eosinophils was reduced following exposure to ultrafine particles in exercising asthmatics 0-21 h post-exposure. A decrease in total leukocyte count was observed following ultrafine particle exposure in exercising healthy and asthmatic subjects. |

| Study | Pollutant | Exposure | Findings |
|---|--|--|--|
| Reference: Gong et al. (2004, 087964) Subjects: 13 older adults with COPD, 6 healthy older adults Gender: COPD: 5 M/ 8 F, Healthy: 2 M/4 F Age: COPD: avg 68 yrs, Healthy: avg 73 yrs | Fine CAPs (Los Angeles) Particle Size: 85% of mass between 0.1 and 2.5 μm Concentration: Mean: 194 $\mu\text{g}/\text{m}^3$, Range: 135-229 $\mu\text{g}/\text{m}^3$ | Exposures to CAPs and filtered air (randomized crossover) conducted for 2 h with intermittent light exercise (four 15-min periods). Exposures were separated by at least 2 wks. Time to analysis: Immediately following exposure as well as 4 and 22 h post-exposure. | SDNN shown to decrease following CAPs exposure relative to filtered air in healthy older adults (4-22 h post-exposure). No CAPs-induced changes in HRV were observed in older adults with COPD. Ectopic heart beats were observed to increase slightly with CAPs relative to filtered air among healthy subjects, but decreased among subjects with COPD. Exposure to CAPs did not affect platelet or white blood cell count, or levels of fibrinogen, vWF, or factor VII. |
| Reference: Gong et al. (2004, 055628) Subjects: 12 adult asthmatics, 4 healthy adults Gender: Asthmatics: 4 M/8 F, Healthy: 2 M/2 F Age: Asthmatics: avg 38 yrs, Healthy: avg 32 yrs | Coarse CAPs (Los Angeles) Particle Size: 80% of mass between 2.5 and 10 μm , 20% of mass < 2.5 μm Concentration: Mean: 157 $\mu\text{g}/\text{m}^3$, Range: 56-218 $\mu\text{g}/\text{m}^3$ | Exposures to CAPs and filtered air (randomized crossover) conducted for 2 h with intermittent light exercise (four 15-min periods). Exposures were separated by at least 2 wks. Time to analysis: Immediately following exposure as well as 4 and 22 h post-exposure. | SDNN shown to decrease following CAPs exposure relative to filtered air in healthy adults (4-22 h post-exposure). Decrease in PNN50 also observed in healthy adults at 4 h post-exposure. No CAPs-induced decreases in HRV demonstrated in asthmatics. |
| Reference: Gong et al. (2008, 156483) Subjects: 14 adult asthmatics, 17 healthy adults Gender: Asthmatics: 9 M/5 F, Healthy: 5 M/12 F Age: Asthmatics: 34 \pm 12 yrs, Healthy: 24 \pm 8 yrs | Ultrafine CAPs (Los Angeles) Particle Number/Count: 145,000/ cm^3 , Range 39,000-312,000/ cm^3 Concentration: Mean: 100 $\mu\text{g}/\text{m}^3$, Range: 13-277 $\mu\text{g}/\text{m}^3$ | Subjects exposed for 2 h during intermittent exercise (15-min periods) to both CAPs and filtered air in random order. The first 7 subjects underwent whole body exposure, while the remaining subjects were exposed through a facemask. Facemask exposures had higher particle counts but lower particle mass than whole body exposures. Exposures were separated by at least 2 wks. Time to analysis: Immediately following exposure as well as 4 and 22 h post-exposure. | Relative to filtered air, exposure to ultrafine CAPs resulted in a transient decrease in LF power 4 h post-exposure. This effect of CAPs on HRV was not influenced by health status. CAPs exposure was not observed to affect any other measures of HRV, blood pressure, or blood markers of inflammation or coagulation. There were no differences in response observed between facemask and whole body exposures. |
| Reference: Graff et al. (2009, 191981) Subjects: 14 healthy adults Gender: 8 M/6 F Age: 20-34 yrs | Coarse CAPs (Chapel Hill, NC) Concentration: 89 \pm 49.5 $\mu\text{g}/\text{m}^3$ (estimated inhaled dose \square 67% of measured particle mass) | Subjects exposed for 2 h with intermittent exercise (15-min periods) to coarse CAPs and filtered air in a randomized crossover design. Exposures were separated by at least 2 mos. Time to analysis: 0-1 and 20 h post-exposure. | At 20 h post-exposure, tPA was observed to decrease by 32.9% from baseline (pre-exposure) per 10 $\mu\text{g}/\text{m}^3$ increase in CAPs concentration ($p = 0.01$). D-dimer concentration decreased 11.3% per 10 $\mu\text{g}/\text{m}^3$, a change of marginal statistical significance ($p = 0.07$). No other coarse CAPs-induced changes in blood biomarkers of coagulation (e.g., vWF, factor VII, plasminogen, fibrinogen, or PAI-1) or inflammation (e.g., CRP) were observed. At 20 h post-exposure, overall HRV (SDNN) was shown to decrease by 14.4% relative to pre-exposure measurements per 10 $\mu\text{g}/\text{m}^3$ increase in CAPs concentration. No other changes in HRV were observed following exposure to coarse CAPs. |

| Study | Pollutant | Exposure | Findings |
|---|---|---|---|
| Reference: Huang et al. (2003, 087377) Subjects: 38 healthy adults Gender: 36 M/2 F Age: Avg 26.2 ± 0.7 yrs | Fine CAPs (Chapel Hill, NC) Concentration: 23.1-311.1 µg/m ³ | Subjects exposed to CAPs (n = 30) or filtered air (n = 8) for 2 h with intermittent exercise (subjects did not serve as their own controls). Component data of CAPs was available for 37 of the 38 subjects. Time to analysis: 18 h after exposure. | The increase in blood fibrinogen following exposure to fine CAPs reported by Ghio et al. (2000, 012140) was shown to be associated with copper, zinc, and vanadium content in the CAPs. |
| Reference: Larsson et al. (2007, 189320) Subjects: 16 healthy adults Gender: 10 M/6 F Age: 19-59 yrs | Traffic particles (road tunnel) Particle Size: PM _{2.5} , PM ₁₀ ; PM _{2.5} mass constituted ~36% of PM ₁₀ mass Particle Number/Count: 20-1,000 nm: 1.1 × 10 ⁵ /cm ³ , < 100 nm: 0.85 × 10 ⁵ /cm ³ Concentration: PM _{2.5} -46-81 µg/m ³ ; PM ₁₀ -130-206 µg/m ³ | Exposures were conducted for 2 h with intermittent exercise in a room adjacent to a busy road tunnel. Study used a randomized crossover design with each subject also exposed to normal air (control). Exposures were separated by 3-10 wks. No exposures to filtered air were conducted. Other traffic emissions measured: NO (874 µg/m ³), NO ₂ (230 µg/m ³), CO (5.8 µg/m ³ reported, likely 5.8 mg/m ³). Time to analysis: 14 h post-exposure. | No change in plasma levels of fibrinogen or PAI-1 observed 14 h post-exposure. |
| Reference: Lucking et al. (2008, 191993) Subjects: 20 healthy adults Gender: M Age: 21-44 yrs | DE Protocol 1 (n=8): idling Deutz diesel engine (F3M2011, 2.2 L, 500 rpm) using gas oil Protocol 2 (n=12): idling Volvo diesel engine (TD45, 4.5 L, 4 cylinders, 680 rpm) using Gasoil E10 Particle Number/Count: Protocol 1: 1.2 × 10 ⁶ /cm ³ ; Protocol 2: 1.26 × 10 ⁶ /cm ³ Concentration: Protocol 1: 348 µg/m ³ , Protocol 2: 330 µg/m ³ | In both protocols, exposures were conducted with intermittent exercise (15-min periods) to DE and filtered air in a randomized crossover design with exposures separated by at least one wk. Protocol 1 (n=8): Exposures conducted for 2 h. Other diesel emissions measured: NO _x (0.58 ppm), NO ₂ (0.23 ppm), NO (0.36 ppm), CO (3.54 ppm), total hydrocarbon (2.8 µg/m ³). Time to analysis: 6 h post-exposure. Protocol 2 (n=12): Exposures conducted for 1h. Other diesel emissions measured: NO _x (2.78 ppm), NO ₂ (0.62 ppm), NO (2.15 ppm), CO (3.08 ppm), total hydrocarbon (1.58 µg/m ³). Time to analysis: 2 and 6 h post-exposure. | Thrombus formation was observed to increase with diesel 2 and 6 h post-exposure using an ex vivo perfusion chamber. Both platelet-neutrophil and platelet-monocyte aggregates increased relative to filtered air 2 h following exposure to diesel (only evaluated in Protocol 2). Plasma concentrations of soluble CD40L were also observed to increase with diesel. Exposure to diesel was not shown to affect total leukocyte, monocyte, or platelet counts. |
| Reference: Lund et al. (2009, 191159) Subjects: 10 healthy adults Gender: 4 M/6 F Age: 18-40 yrs | DE Idling Cummins diesel engine (5.9 L) using commercial No. 2 fuel Particle Size: MMAD 0.10 µm Concentration: 100 µg/m ³ | Subjects exposed for 1 h with intermittent exercise (15-min periods) to DE and filtered air in a randomized crossover study design. Other diesel emissions measured: NO _x (4.7 ppm), NO ₂ (0.8 ppm), CO (2.8 ppm), total hydrocarbons (2.4 ppm). Time to analysis: 30 min and 24 h post-exposure. | Exposure to diesel resulted in an increase in MMP-9 plasma concentration and activity as well as an increase in endothelin-1 plasma concentration at both 30 min and 24 h post-exposure. |
| Reference: Lundback et al. (2009, 191967) Subjects: 12 healthy adults Gender: M Age: 21-30 yrs | DE Idling Volvo diesel engine (TD45, 4.5 L, 4 cylinders, 680 rpm) using Gasoil E10 Particle Number/Count: 1.26 × 10 ⁶ /cm ³ Concentration: 330 µg/m ³ | Subjects exposed for 1 h with intermittent exercise (15-min periods) to DE and filtered air in a randomized crossover study design. Exposures were separated by at least one wk. Other diesel emissions measured: NO _x (2.78 ppm), NO ₂ (0.62 ppm), NO (2.15 ppm), CO (3.08 ppm), total hydrocarbon (1.58 µg/m ³). Time to analysis: 10, 20, 30, and 40 min post-exposure. | Diesel-induced increase in arterial stiffness (increases in augmentation pressure and augmentation index, as well as decrease in time to wave reflection) observed at 10 and 20 min post-exposure using radial artery pulse wave analysis. No effect of diesel observed on carotid-femoral pulse wave velocity which was assessed 40 min post-exposure, but not at earlier time points. No effect of diesel observed on blood pressure 10-30 min post-exposure. |

| Study | Pollutant | Exposure | Findings |
|---|---|---|--|
| Reference: Mills et al. (2005, 188557) Subjects: 30 healthy adults Gender: M Age: 20-38 yrs | DE Idling 1991 Volvo diesel engine (TD45, 4.5 L, 4 cylinders, 680 rpm) Particle Number/Count: $1.2 \times 10^6/\text{cm}^3$ Concentration: $300 \mu\text{g}/\text{m}^3$ | Subjects exposed for 1 h with intermittent exercise (15-min periods) to DE and filtered air in a randomized crossover study design. Exposures were separated by two wks. Other diesel emissions measured: NO_2 (1.6 ppm), NO (4.5 ppm), CO (7.5 ppm), total hydrocarbon (4.3 ppm), formaldehyde (0.26 $\mu\text{g}/\text{m}^3$). Time to analysis: 2-4 h post-exposure for 15 subject; 6-8 h post-exposure for the other 15 subjects. | Forearm blood flow increase (induced by bradykinin, acetylcholine, and sodium nitroprusside) was attenuated by DE 2 and 6 h post-exposure. A 6 mmHg increase in diastolic blood pressure ($p = 0.08$) 2 h following exposure to DE was observed relative to filtered air control. Bradykinin-induced release of t-PA was attenuated by diesel exposure 6 h post-exposure. DE did not affect the release of t-PA 2 h post-exposure. No diesel-induced changes in serum IL-6 or TNF- α observed 6 h post-exposure. |
| Reference: Mills et al. (2007, 091206) Subjects: 20 older adults with prior myocardial infarction Gender: M Age: 60 ± 1 yrs | DE Idling 1991 Volvo diesel engine (TD45, 4.5 L, 4 cylinders, 680 rpm) using low sulfur gas-oil E10 Particle Size: Median particle diameter 54 nm, Range 20-120 nm Particle Number/Count: $1.26 \times 10^6/\text{cm}^3$ Concentration: $300 \mu\text{g}/\text{m}^3$ | Subjects exposed for 1 h with intermittent exercise (15-min periods) to DE and filtered air in a randomized crossover study design. Exposures were separated by at least two wks. Other diesel emissions measured: NO_x (4.45 ppm), NO_2 (1.01 ppm), NO (3.45 ppm), CO (2.9 ppm), total hydrocarbon (2.8 ppm). Time to analysis: During exposure and 6-8 h post-exposure. | A greater increase in exercise induced ST-segment depression and ischemic burden was observed during exposure to DE than clean air. No diesel-induced effects on vasomotor dysfunction observed 6 h post-exposure. Bradykinin-induced release of t-PA was attenuated by diesel exposure relative to filtered air 6 h post-exposure. Effect of diesel on t-PA release was not evaluated at earlier times post-exposure. No diesel-induced changes in blood leukocyte counts or serum C-reactive protein 6 h post-exposure. |
| Reference: Mills et al. (2008, 156766) Subjects: 12 adults with coronary heart disease, 12 healthy adults Gender: M Age: CHD: 59 ± 2 yrs, Healthy: 54 ± 2 yrs | Fine CAPs (Edinburgh, Scotland, UK) Particle Size: Mean $1.23 \mu\text{m}$ Particle Number/Count: $99,400/\text{cm}^3$ Concentration: $190 \pm 37 \mu\text{g}/\text{m}^3$ | Exposures conducted for 2 h with intermittent exercise. Subjects exposed to CAPs and filtered air using a randomized crossover design with exposures separated by at least 2 wks. Time to analysis: 2, 6-8, and 24 h post-exposure. | CAPs exposure had no significant effect on vascular function in healthy adults or adults with coronary heart disease 6-8 h post-exposure (i.e., no change in forearm blood flow as assessed using venous occlusion plethysmography). The authors attributed this lack of response to a low concentration of combustion-derived particles. Small increase in blood platelet and monocyte concentration observed following CAPs exposure. Exposure to CAPs did not affect serum CRP concentration or total leukocyte or neutrophil count. |
| Reference: Peretz et al. (2007, 189082) Subjects: 5 healthy adults Gender: M Age: 20-31 yrs | DE 2002 Cummins B-series diesel engine (6BT5.9G6, 5.9 L); operating at 75% of rated capacity Concentration: Fine PM 50, 100, 200 $\mu\text{g}/\text{m}^3$ | Subjects exposed for 2 h at rest to filtered air and each of the three DE particle concentrations in a randomized crossover study design. Exposures were separated by at least 2 wks. Other diesel emissions measured, 200 $\mu\text{g}/\text{m}^3$ exposure: NO_2 (23 ppb), NO (1.75 ppm), CO (1.58 ppm). Time to analysis: 6 and 22 h after the start of exposure. | PBMC expression of 10 genes involved in the inflammatory response were observed to be significantly affected by exposure to DE at the highest concentration tested (8 upregulated, 2 downregulated) 6 h after the start of exposure. The expression of 4 genes (1 upregulated, 3 downregulated) associated with the inflammatory response showed significant changes 22 h after diesel exposure. PBMC expression of 5 genes involved in the oxidative stress pathways showed significant changes at 6 h after the start of diesel exposure at the highest concentration tested (4 upregulated, 1 downregulated). 7 genes involved in the oxidative stress pathways showed significant changes at 22 h following exposure (4 upregulated, 3 downregulated). |

| Reference: Peretz et al. (2008, 156854) Subjects: 17 adults with metabolic syndrome, 10 healthy adults Gender: Metabolic syndrome: 11 M/6 F, Healthy: 8 M/2 F Age: Metabolic syndrome: 20-48 yrs, Healthy: 20-42 yrs | DE 2002 Cummins B-series diesel engine (6BT5.9G6, 5.9 L) using No. 2 undyed on-highway fuel; operating at 75% of rated capacity Particle Size: Median particle diameter 1.04 μm Concentration: Fine PM 100, 200 $\mu\text{g}/\text{m}^3$ | Subjects exposed for 2 h at rest to both concentrations of DE as well as filtered air in a randomized crossover design. Exposures were separated by at least 2 wks. Other diesel emissions measured, 100 $\mu\text{g}/\text{m}^3$ exposure: NO ₂ (16.5 ppb), NO (0.96 ppm), CO (0.51 ppm); 200 $\mu\text{g}/\text{m}^3$ exposure: NO ₂ (24.7 ppb), NO (1.54 ppm), CO (0.89 ppm). Time to analysis: Immediately following exposure (within 30 min post-exposure) and 3 h from the start of exposure. | Exposure to 200 $\mu\text{g}/\text{m}^3$ elicited a statistically significant decrease in brachial artery diameter relative to filtered air immediately following exposure. A smaller decrease in brachial artery diameter was also observed following exposure to DE at 100 $\mu\text{g}/\text{m}^3$. Plasma levels of endothelin-1 were observed to increase following DE exposure (200 $\mu\text{g}/\text{m}^3$). The observed effects were more pronounced in healthy subjects than in subjects with metabolic syndrome. DE did not affect endothelium-dependent flow-mediated dilatation. No effect of DE on blood pressure was demonstrated immediately following exposure. |
| Reference: Peretz et al. (2008, 156855) Subjects: 13 adults with metabolic syndrome, 3 healthy adults Gender: Metabolic syndrome: 8 M/5 F, Healthy: 3 M/0 F Age: Metabolic syndrome: 31-48 yrs, Healthy: 24-39 yrs | DE 2002 Cummins B-series diesel engine (6BT5.9G6, 5.9 L) using No. 2 undyed on-highway fuel; operating at 75% of rated capacity Concentration: Fine PM 100, 200 $\mu\text{g}/\text{m}^3$ | Subjects exposed for 2 h at rest to both concentrations of DE as well as filtered air in a randomized crossover design. Exposures were separated by at least 2 wks. Other diesel emissions measured, 100 $\mu\text{g}/\text{m}^3$ exposure: NO ₂ (20.6 ppb), NO (0.95 ppm), CO (0.47 ppm); 200 $\mu\text{g}/\text{m}^3$ exposure: NO ₂ (28.3 ppb), NO (1.63 ppm), CO (0.74 ppm). Time to analysis: 1, 3, 6, and 22 h from the start of exposure. | Exposure to 200 $\mu\text{g}/\text{m}^3$ increased HF power and decreased the LF/HF ratio 1h post-exposure; however, this effect was not consistent across subjects. No effect of DE was observed at later time points. Subjects with metabolic syndrome did not experience greater changes in HRV than healthy subjects. |
| Reference: Power et al. (2008, 191982) Subjects: 5 adults with mild-to-moderate allergic asthma Gender: 1 M/4 F Age: 28-51 yrs | Carbon and ammonium nitrate particles Concentration: With co-exposure to 0.2ppm O ₃ : 255 $\mu\text{g}/\text{m}^3$, Without co-exposure to 0.2ppm O ₃ : 313 $\mu\text{g}/\text{m}^3$ | Subjects exposed for 4 h with intermittent exercise (30-min periods) to filtered air, particles, and particles + ozone in a crossover study design. Exposures were separated by at least 3 wks. Time to analysis: 3 h 40 min from the start of exposure. | Time and frequency domain HRV parameters were not affected by particle exposure relative to filtered air. However, exposure to particles with ozone resulted in a significant decrease in SDNN as well high and low frequency power normalized to the difference between total and very low frequency power. |

| Reference: Routledge et al. (2006, 088674) Subjects: 20 older adults with coronary artery disease, 20 healthy older adults Gender: CAD: 17 M/3 F, Healthy: 10 M/10 F Age: CAD: 52-74 yrs, Healthy: 56-75 yrs | Ultrafine carbon Particle Size: < 10-300 nm; mode at 20-30 nm Concentration: Ultrafine carbon: 50 $\mu\text{g}/\text{m}^3$; SO ₂ : 200ppb | Exposures conducted (head dome system) to filtered air, ultrafine carbon, SO ₂ , and ultrafine carbon + SO ₂ for 1 h at rest using a randomized crossover study design. Time to analysis: Immediately following exposure as well as 3 and 23 h post-exposure. | No PM-induced changes in HRV observed among subjects with coronary artery disease. Among healthy subjects, small increase in HRV (RR, SDNN, rMSSD, and LF power) demonstrated immediately post-carbon exposure. Relative to filtered air control, exposure to ultrafine carbon did not significantly affect blood pressure in healthy adults or adults with coronary artery disease 0-3 h post-exposure. Exposure to ultrafine carbon, either alone or with SO ₂ , did not affect plasma levels of fibrinogen or D-dimer at 3 or 23 h post-exposure. Exposure to ultrafine carbon did not affect peripheral blood leukocyte count or C-reactive protein levels 3 or 23 h post-exposure. |
| Reference: Rundell and Caviston (2008, 191986) Subjects: 15 healthy college athletes Gender: M Age: Avg 19.5 yrs | Gasoline emissions 2.5 hp gasoline engine running 10 s each min during exposure and in the min prior to exposure Particle Size: PM _{1.0} Particle Number/Count: Trial 1: 336,730 \pm 149,206/cm ³ ; Trial 2: 396,200 \pm 82,564/cm ³ | Subjects were exposed twice to both clean air and dilute gasoline exhaust during 6-min periods of maximal exercise on a cycle ergometer. Clean air exposures occurred first and were separated by 3 days. Gasoline exhaust exposures were also separated by 3 days, with the first occurring 7 days after the second clean air exposure. Other emissions measured: CO (6.3 \pm 3.4 ppm). Time to analysis: 6 min | There was no difference in total work done (kJ) between the clean air exposures or between the clean air exposures and the first exposure to gasoline exhaust. However, the second gasoline exhaust exposure was demonstrated to significantly decrease work accumulated over the 6min exercise period compared with either of the other exposure conditions (p < 0.01). |
| Reference: Samet et al. (2007, 156940) Subjects: Ultrafine CAPs: 20 healthy adults, Coarse CAPs: 14 healthy adults Gender: Ultrafine CAPs: 11 M/9 F, Coarse CAPs: 8 M/6 F Age: Ultrafine CAPs: 18-35 yrs, Coarse CAPs: 18-35 yrs | CAPs (Chapel Hill, NC) Particle Size: Ultrafine 0.049 \pm 0.009 μm ; Coarse 3.59 \pm 0.58 μm Concentration: Ultrafine 47.0 \pm 20.2 $\mu\text{g}/\text{m}^3$; Coarse 89.0 \pm 49.5 $\mu\text{g}/\text{m}^3$ | Preliminary report comparing effects of controlled exposures to coarse, fine, and ultrafine CAPs among healthy adults (3 separate studies). A randomized crossover design was used in evaluating effects of coarse CAPs (n = 14) and ultrafine CAPs (n = 20) relative to filtered air following 2-h exposures with intermittent exercise. Results compared with previous study of controlled exposure to fine CAPs (Chapel Hill, NC) where subjects did not serve as their own controls (Ghio et al., 2000, 012140). Time to analysis: 0-20 h post-exposure. | Statistically significant decrease in SDNN observed 20 h following exposure to coarse CAPs relative to filtered air. Subjects in the high ultrafine CAPs group experienced a decrease in SDNN based on an analysis of 24 h ambulatory Holter monitoring relative to filtered air. Fine CAPs did not significantly affect HRV. Increased levels of D-dimer observed 18 h following exposure to ultrafine CAPs. No CAPs-induced changes in plasma factor VII, plasminogen, fibrinogen, PAI-1, vWf, or t-PA. No CAPs-induced changes in C-reactive protein levels were observed. |

| Reference: Samet et al. (2009, 191913) Subjects: 19 healthy adults Gender: 10 M/9 F Age: 18-35 yrs | Ultrafine CAPs (Chapel Hill, NC) Particle Size: < 0.16 μm Particle Number/Count: 120,662 \pm 48,232 particles/cm ³ Concentration: 49.8 \pm 20 $\mu\text{g}/\text{m}^3$ | Subjects exposed for 2 h with intermittent 15 periods of exercise to UF CAPs and filtered air using a randomized crossover study design. Time to analysis: Immediately following exposure and 1 and 18 h post-exposure. | UF CAPs exposure resulted in an increase in plasma concentrations of D-dimer both immediately following exposure (20.6% increase per 10 ⁵ particles/cm ³) as well as 18 h post-exposure (18.2% increase per 10 ⁵ particles/cm ³). Plasma concentration of PAI1 also increased with UF CAPs, although this increase was not statistically significant (24% increase, $p = 0.1$). No UF CAPs-induced changes observed in plasma concentrations of tPA, vWF, CRP, fibrinogen, plasminogen, or Factor VII. HF and LF power were both observed to increase with UF CAPs exposure relative to filtered air at 18 h post-exposure (41.8% and 36%, respectively, per 10 ⁵ particles/cm ³ increase in UF CAPs). UF CAPs expressed as mass concentration was not observed have a statistically significant effect in HF total power. UF CAPs was not observed to affect time domain measures of HRV over 24 h. The QT interval was shown to decrease both immediately following and at 18 h post exposure (not statistically significant immediately following exposure). |
| Reference: Shah et al. (2008, 156970) Subjects: 16 healthy adults Age: 26.9 \pm 6.9 yrs | Ultrafine elemental carbon Particle Number/Count: 10.8 \pm 1.7 $\times 10^6$ /cm ³ Concentration: 50 $\mu\text{g}/\text{m}^3$ | Exposures conducted via mouthpiece for 2 h with intermittent exercise to filtered air and ultrafine carbon in a randomized crossover study design. Time to analysis: Immediately following exposure as well as 3.5, 21, and 45 h post-exposure. | Exposure to ultrafine carbon attenuated peak forearm blood flow after ischemia relative to filtered air 3.5 h post-exposure. Venous nitrate levels were significantly lower at 21 h following exposure to UF carbon compared with filtered air exposure. PM exposure was not observed to affect blood pressure relative to filtered air at times 0-45 h post-exposure. |
| Reference: Tornqvist et al. (2007, 091279) Subjects: 15 healthy adults Gender: M Age: 18-38 yrs | DE Idling 1991 Volvo diesel engine (TD45, 4.5 L, 4 cylinders, 680 rpm) Concentration: 300 $\mu\text{g}/\text{m}^3$ | Subjects exposed for 1h with intermittent exercise (15-min periods) to DE and filtered air in a randomized crossover study design. Exposures were separated by at least two wks. Other diesel emissions measured: NO _x (4.44 ppm), NO ₂ (0.82 ppm), NO (3.62 ppm), total hydrocarbon (2.21 ppm). Time to analysis: 24 h post-exposure. | DE was observed to significantly attenuate endothelium-dependent vasodilation 24 h post-exposure. Endothelium-independent vasodilation was not affected by diesel exposure. Exposure to DE did not affect blood pressure relative to filtered air 24 h after exposure. DE significantly increased plasma levels of IL-6 and TNF- α 24 h following exposure. Exposure to diesel resulted in an increase in total antioxidant capacity of plasma relative to filtered air 24 h post-exposure. |
| Reference: Urch et al. (2004, 055629) Subjects: 24 healthy adults Gender: 14 M/10 F Age: 35 \pm 10 yrs | Fine CAPs (Toronto) Concentration: 150 $\mu\text{g}/\text{m}^3$ (range 101-257 $\mu\text{g}/\text{m}^3$) with 120 ppb ozone | Exposures conducted through a facemask which covered the subject's nose and mouth. Subjects were exposed to CAPs + ozone and filtered air for 2 h at rest in a randomized crossover study design. Exposures were separated by at least 2 days. Time to analysis: Immediately following exposure. | CAPs + ozone exposure resulted in a significant decrease in brachial artery diameter immediately post-exposure (Brook et al., 2002, 024987), which was demonstrated to be associated with both the organic and elemental carbon fractions of the CAPs. |
| Reference: Urch et al. (2005, 081080) Subjects: 23 healthy adults Gender: 13 M/10 F Age: 32 \pm 10 yrs | Fine CAPs (Toronto); Concentration: 150 $\mu\text{g}/\text{m}^3$ (range 102-214 $\mu\text{g}/\text{m}^3$) with 120 ppb ozone | Exposures conducted through a facemask which covered the subject's nose and mouth. Subjects were exposed to CAPs + ozone and filtered air for 2 h at rest in a randomized crossover study design. Time to analysis: Every 30 min during exposure, with the final measurement made immediately prior to the end of the exposure. | An increase in diastolic blood pressure of 6 mmHg was observed at the end of CAPs + ozone exposure, which was statistically different from the change in blood pressure experienced during exposure to filtered air (1 mmHg). This effect was associated with the organic fraction of PM _{2.5} . |

| Reference: Zareba et al. (2009, 190101) Subjects: 24 healthy adults Gender: 12 M/12 F Age: 18-40 yrs | Ultrafine elemental carbon Particle Size: Count median diameter 25 nm Particle Number/Count: $2 \times 10^6/\text{cm}^3$ ($10 \mu\text{g}/\text{m}^3$), $7 \times 10^9/\text{cm}^3$ ($25 \mu\text{g}/\text{m}^3$) Concentration: $10 \mu\text{g}/\text{m}^3$; $25 \mu\text{g}/\text{m}^3$ | Protocol 1 (n = 12, 6 M/6 F): Subjects exposed to $10 \mu\text{g}/\text{m}^3$ UF carbon and filtered air for 2 h at rest in a randomized crossover design. Exposures were separated by at least 2 wks. Protocol 2 (n = 12, 6 M/6 F): Subjects exposed to $10 \mu\text{g}/\text{m}^3$, $25 \mu\text{g}/\text{m}^3$, and filtered air for 2 h with intermittent exercise (15-min periods) in a restricted randomized crossover design (all subjects exposed to $10 \mu\text{g}/\text{m}^3$ before $25 \mu\text{g}/\text{m}^3$). Exposures were separated by at least 2 wks. Time to analysis (both protocols): Immediately following exposure and 3.5 and 21 h post-exposure. | Exposure to $10 \mu\text{g}/\text{m}^3$ at rest resulted in no change in HRV frequency domain parameters relative to filtered air exposure. Time domain parameters were observed to increase slightly with UF carbon exposure ($10 \mu\text{g}/\text{m}^3$ at rest), however, only the increase in rMSSD was statistically significant ($p = 0.032$). Some trends toward less shortening of QT interval, increase in ST segment, and increase in variability of repolarization (variability of T wave complexity) were observed with exposure to $10 \mu\text{g}/\text{m}^3$ at rest, none of which were statistically significant. In Protocol 2, exposure to $10 \mu\text{g}/\text{m}^3$ UF carbon was observed to slightly increase HRV time domain parameters as was demonstrated in Protocol 1. However, this was not observed at the higher concentration ($25 \mu\text{g}/\text{m}^3$). As with exposure at rest, exposure to UF carbon during exercise was observed to affect repolarization (reduction in QT duration and increase in T-wave amplitude), although this effect was not statistically significant. |

Table C-2. Respiratory effects

| Reference: Alexis et al. (2006, 088636) Subjects: 9 healthy adults Gender: 3 M/6 F Age: 18-35 yrs | Coarse fraction particles (Chapel Hill, NC) Heat-treated (biologically inactive) and non-heated particles Particle Size: MMAD $5 \mu\text{m}$ Concentration: 0.65 mg per subject | Subjects were administered heat-treated $\text{PM}_{2.5-10}$, non-heated $\text{PM}_{2.5-10}$, and 0.9% saline (control) via nebulization in a randomized crossover study design. Exposures were separated by at least 1 wk. Time to analysis: 2-3 h post-inhalation. | Both heat-treated and non-heated coarse PM were observed to increase neutrophil counts in induced sputum 2-3 h post-inhalation. Biologically active PM (non-heated) induced an increase expression of macrophage $\text{TNF-}\alpha$ mRNA, eotaxin, and immune surface phenotypes on macrophages (mCD14, CD11b/CR3, and HLA-DR). |
| Reference: Barregard et al. (2008, 155675) Subjects: 13 healthy adults Gender: 6 M/ 7 F Age: 20-56 yrs | Wood smoke Particle Size: Session 1: geometric mean diameter 42 nm, Session 2: geometric mean diameter 112 nm Particle Number/Count: Session 1: $180,000/\text{cm}^3$; Session 2: $95,000/\text{cm}^3$ Concentration: Session 1: median $279 \mu\text{g}/\text{m}^3$; Session 2: median $243 \mu\text{g}/\text{m}^3$ | Subjects exposed in two groups for 4 h to filtered air, followed a wk later by a 4-h exposure to wood smoke. Exposures conducted with two 25-min periods of light exercise. Other measured combustion products: Session 1: NO_2 (0.08 ppm), CO (13 ppm), formaldehyde ($114 \mu\text{g}/\text{m}^3$), acetaldehyde ($75 \mu\text{g}/\text{m}^3$), benzene ($30 \mu\text{g}/\text{m}^3$), 1,3-butadiene ($6.3 \mu\text{g}/\text{m}^3$); Session 2: NO_2 (0.09 ppm), CO (9.1 ppm), formaldehyde ($64 \mu\text{g}/\text{m}^3$), acetaldehyde ($40 \mu\text{g}/\text{m}^3$), benzene ($20 \mu\text{g}/\text{m}^3$), 1,3-butadiene ($3.9 \mu\text{g}/\text{m}^3$). Time to analysis: Immediately following exposure as well as 3 and 20 h post-exposure. | Relative to filtered air, exposure to wood smoke was observed to increase levels of eNO 3 h post-exposure. Serum Clara cell protein increased 20 h after wood smoke exposure. Wood smoke was observed to increase levels of malondialdehyde in breath condensate immediately after as well as 20 h post-exposure. Effects of wood smoke on eNO and malondialdehyde levels were similar between the two sessions of wood smoke exposure. However, serum Clara cell protein was significantly increased with wood smoke in session 1 (higher particle count) but not in session 2. |
| Reference: Bastain et al. (2003, 098690) Subjects: 18 nonsmoking adults with positive allergy skin test to short ragweed Gender: 7 M/11 F Age: 18-38 yrs | DEP Isuzu diesel engine, 4 cylinder, 4JB1 Concentration: 0.3 mg in $200 \mu\text{l}$ saline | Subjects underwent nasal provocation challenge (intranasal spray) with allergen and either DEP or placebo (saline) in a randomized crossover study design. Challenges were separated by 30 days. This protocol was then repeated 30 days after the last exposure. Time to analysis: 24 h post-exposure and 4 and 8 days after exposure. | DEP significantly increased allergic responses to short ragweed. Relative to allergen + placebo, allergen + DEP increased allergen specific IgE 4days following exposure, and increased IL-4 1 day post-exposure. The enhancement of allergic response with DEP was observed to be reproducible within subjects. |

| Reference: Beckett et al. (2005, 156261) Subjects: 12 healthy adults Gender: 6 M/6 F Age: 23-52 yrs | Ultrafine and fine zinc oxide Particle Size: UF: < 0.1 μm ; Fine: 0.1-1.0 μm Particle Number/Count: UF: $4.6 \times 10^7/\text{cm}^3$; Fine: $1.9 \times 10^9/\text{cm}^3$ Concentration: 500 $\mu\text{g}/\text{m}^3$ | Subjects exposed via mouthpiece for 2 h during rest to filtered air, ultrafine, and fine zinc oxide in a randomized crossover study design. Exposures were separated by at least 3 wks. Time to analysis: 11 and 24 h after exposure. | No changes observed in neutrophil count in induced sputum. No PM (zinc oxide)-induced changes in respiratory symptoms observed 0-24 h post-exposure. |
| Reference: Behndig et al. (2006, 156286) Subjects: 15 healthy adults Gender: 8 M/7 F Age: 21-27 yrs | DE Idling 1991 Volvo diesel engine (TD45, 4.5 L, 4 cylinders, 680 rpm) Particle Size: PM ₁₀ ; majority of PM mass made up of particles < 1 μm in diameter Concentration: 100 $\mu\text{g}/\text{m}^3$ | Exposures conducted for 2 h with intermittent exercise to both DE and filtered air in a randomized crossover design. Exposures were separated by at least 3 wks. Other diesel emissions measured: NO _x (1.8 ppm), NO ₂ (0.4 ppm), NO (1.3 ppm), CO (10.4 ppm), total hydrocarbons (1.3 ppm). Time to analysis: 18 h post-exposure. | Exposure to DE increased neutrophil and mast cell numbers in bronchial mucosa at 18 h post-exposure. Neutrophils, IL-8, and myeloperoxidase observed to increase in bronchial lavage fluid following exposure relative to filtered air. No inflammatory response observed in the alveolar compartment. Exposure to DE increased urate and reduced glutathione bronchoalveolar lavage at 18 h post-exposure. |
| Reference: Blomberg et al. (2005, 191991) Subjects: 15 older adults (former smokers) with COPD Age: 56-72 yrs | DE Concentration: 300 $\mu\text{g}/\text{m}^3$ | Subjects exposed for 1 h with intermittent exercise to DE and filtered air in a randomized crossover study design. Time to analysis: 6 and 24 h post-exposure. | DE was not observed to affect levels of Clara cell protein in peripheral blood at 6 and 24 h post-exposure. |
| Reference: Bosson et al. (2007, 156286) Subjects: 16 healthy adults Gender: 7 M/9 F Age: 20-28 yrs | DE Idling Volvo diesel engine Concentration: PM 300 $\mu\text{g}/\text{m}^3$ followed by exposure to filtered air or 0.2 ppm ozone | Subjects exposed to DE for 1 h followed 5 h later by a 2-h exposure to either filtered air or ozone (0.2 ppm) using a randomized crossover study design. All exposures were conducted with subjects engaged in intermittent exercise. Time to analysis: 18 h after second exposure (filtered air or ozone). | The percentage of neutrophils and concentration of myeloperoxidase in induced sputum (18 h post-ozone/air exposure) was significantly higher following diesel + ozone than diesel + air. |
| Reference: Bosson et al. (2008, 156287) Subjects: 14 healthy adults Gender: 9 M/5 F Age: 21-29 yrs | DE Idling 1991 Volvo diesel engine (TD45, 4.5 L, 4 cylinders) Concentration: PM 300 $\mu\text{g}/\text{m}^3$ or filtered air followed by exposure to 0.2 ppm ozone | Subjects exposed to DE or filtered air for 1h followed 5 h later by a 2-h exposure to ozone (0.2 ppm) using a randomized crossover study design. All exposures were conducted with subjects engaged in intermittent exercise. Other diesel emissions measured: NO ₂ (0.51 ppm), NO (1.65 ppm), total hydrocarbons (1.18 ppm). Time to analysis: 24 h after the start of the initial exposure. | Neutrophil and macrophage numbers in bronchial wash were significantly increased 16 h following ozone exposure when preceded by exposure to diesel, compared to ozone exposure preceded by exposure to filtered air. |
| Reference: Brauner et al. (2009, 190244) Subjects: 29 healthy adults Gender: 20 M, 9 F Age: M avg 27 yrs, F avg 26 yrs | Urban traffic particles Particle Size: PM _{2.5} , PM _{2.5-10} Particle Number/Count: 6-700 nm: 10,067/cm ³ Concentration: PM _{2.5} : 9.7 $\mu\text{g}/\text{m}^3$, PM _{2.5-10} : 12.6 $\mu\text{g}/\text{m}^3$ | Subjects exposed to urban traffic particles and filtered air for 24 h with and without two 90-min periods of light exercise in a randomized crossover study design. Concentrations of NO _x and NO were low and did not differ between filtered and unfiltered exposures. CO concentrations were higher with filtered air (0.35 and 0.41 ppm), while ozone concentrations were lower with filtered air (12.08 and 4.29 ppb). Time to analysis: 2.5, 6, and 24 h after the start of exposure. | Epithelial membrane integrity and blood-gas barrier permeability, assessed using pulmonary clearance of ^{99m} Tc-labeled diethylenetriamine pentaacetic acid (DTPA), was observed to increase with exercise, but was not affected by exposure to urban particles (2.5 h of exposure). Exposure to urban particles was not shown to affect plasma or urine concentration of Clara cell 16 protein at 6 and 24 h after the start of exposure. No relationship between exposure and pulmonary function was observed at 2.5 h. |
| Reference: Gilliland et al. (2004, 156471) Subjects: 19 adults with allergic rhinitis and positive skin test to ragweed, GSTM1 (14 null, 5 present); GSTT1 (9 null, 10 present); GSTP1 codon 105 variants (13 I/I, 6 I/V, 0 V/V) Gender: 7 M/12 F Age: 20-34 yrs | DEP Isuzu diesel engine, 4 cylinder, 4JB1 Concentration: 0.3 mg DEP in 300 μL saline | Subjects were challenged intranasally with allergen and placebo (saline) as well as allergen plus DEP in saline in a randomized crossover design. Challenges were separated by at least 6 wks. Time to analysis: 10 min, 24 h, and 72 h post-challenge. | Subjects who were GSTM1 null or homozygous for GSTP1 1105 wild-type allele experienced significantly greater increase in nasal IgE and histamine with diesel plus allergen compared to subjects with functional GSTM1 or who were heterozygous for GSTP1 I/V(105). |

| Reference: Gong et al. (2004, 087984) Subjects: 13 older adults with COPD, 6 healthy older adults Gender: COPD: 5 M/ 8 F, Healthy: 2 M/4 F Age: COPD: avg 68 yrs, Healthy: avg 73 yrs | Fine CAPs (Los Angeles) Particle Size: 85% of mass between 0.1 and 2.5 μm Concentration: Mean: 194 $\mu\text{g}/\text{m}^3$, Range: 135-229 $\mu\text{g}/\text{m}^3$ | Exposures to CAPs and filtered air (randomized crossover) for 2 h with intermittent light exercise (four 15-min periods). Exposures were separated by at least 2 wks. Time to analysis: Immediately following exposure as well as 4 and 22 h post-exposure. | No CAPs-induced respiratory symptoms observed in healthy older adults or older adults with COPD at 0, 4, or 22 h post-exposure. Exposure to CAPs did not significantly affect FVC or FEV ₁ . CAPs exposure caused a decrease in arterial oxygen saturation 4 h post-exposure which was more pronounced in healthy older adults than in older adults with COPD. Exposure to CAPs was not observed to affect the levels of white blood cells, columnar epithelial cells, IL-6, or IL-8 in induced sputum. |
| Reference: Gong et al. (2004, 055628) Subjects: 12 adult asthmatics, 4 healthy adults Gender: Asthmatic: 4 M/8 F, Healthy: 2 M/2 F Age: Asthmatic: avg 38 yrs, Healthy: avg 32 yrs | Coarse CAPs (Los Angeles) Particle Size: 80% of mass between 2.5 and 10 μm , 20% of mass < 2.5 μm Concentration: Mean: 157 $\mu\text{g}/\text{m}^3$, Range: 56-218 $\mu\text{g}/\text{m}^3$ | Exposures to CAPs and filtered air (randomized crossover) for 2 h with intermittent light exercise (four 15-min periods). Exposures were separated by at least 2 wks. Time to analysis: Immediately following exposure as well as 4 and 22 h post-exposure. | No effect of CAPs exposure on spirometry or arterial oxygen saturation was observed 0, 4, or 22 h post-exposure. No respiratory symptoms reported 0-22 h post-exposure in either healthy or asthmatic adults. Sputum cell counts at 22 h post-exposure did not differ between CAPs and filtered air. |
| Reference: Gong et al. (2005, 087921) Subjects: 18 older adults with COPD, 6 healthy older adults Gender: COPD: 9 M/9 F, Healthy: 2 M/4 F Age: COPD: avg 72 yrs, Healthy: avg 68 yrs | Fine CAPs (Los Angeles) Concentration: CAPs: 200 $\mu\text{g}/\text{m}^3$; NO ₂ : 0.4 ppm | Each subject was exposed to CAPs, NO ₂ , CAPs + NO ₂ , and filtered air for 2 h with intermittent exercise. Exposure order was not fully counterbalanced as NO ₂ exposures were conducted after the majority of the CAPs and filtered air exposures had been completed. Exposures were separated by at least 2 wks. Time to analysis: Immediately following exposure as well as 4 and 22 h post-exposure. | Exposure to CAPs was observed to decrease maximal mid-expiratory flow and arterial oxygen saturation relative to filtered air 4-22 h post-exposure. This response was more pronounced in healthy older adults than in older adults with COPD. Concomitant exposure to NO ₂ did not enhance the response. No other respiratory responses (symptoms, spirometry, sputum cell counts) were affected by exposure to CAPs. |
| Reference: Gong et al. (2008, 156483) Subjects: 14 adult asthmatics, 17 healthy adults Gender: Asthmatics: 9 M/5 F, Healthy: 5 M/12 F Age: Asthmatics: 34 \pm 12 yrs, Healthy: 24 \pm 8 yrs | Ultrafine CAPs (Los Angeles) Particle Number/Count: 145,000/cm ³ , Range: 39,000-312,000/cm ³ Concentration: Mean: 100 $\mu\text{g}/\text{m}^3$, Range: 13-277 $\mu\text{g}/\text{m}^3$ | Subjects exposed for 2 h during intermittent exercise (15-min periods) to both CAPs and filtered air in random order. The first 7 subjects underwent whole body exposure, while the remaining subjects were exposed through a facemask. Facemask exposures had higher particle counts but lower particle mass than whole body exposures. Exposures were separated by at least 2 wks. Time to analysis: Immediately following exposure as well as 4 and 22 h post-exposure. | No significant differences in respiratory symptoms observed between filtered air and ultrafine CAPs exposures. Individuals exposed to higher particle counts tended to experience greater symptoms with CAPs than with filtered air. An ultrafine CAPs-induced decrease in arterial oxygen saturation (0.5%) was observed at 0, 4, and 22 h post-exposure. A decrease in FEV ₁ (2%) was also observed 22 h post-exposure relative to filtered air. Responses were not significantly different between healthy and asthmatic adults. CAPs exposure was not observed to affect total sputum cell counts or cytokine levels. There were no differences in response observed between facemask and whole body exposures. |
| Reference: Graff et al. (2009, 191981) Subjects: 14 healthy adults Gender: 8 M/6 F Age: 20-34 yrs | Coarse CAPs (Chapel Hill, NC) Concentration: 89 \pm 49.5 $\mu\text{g}/\text{m}^3$ (estimated inhaled dose \square 67% of measured particle mass) | Subjects exposed for 2 h with intermittent exercise (15-min periods) to coarse CAPs and filtered air in a randomized crossover design. Exposures were separated by at least 2 mos. Time to analysis: 0-1 and 20 h post-exposure. | Pulmonary function (FVC, FEV ₁ , and carbon monoxide diffusing capacity) was not affected by exposure to coarse CAPs either immediately following exposure or 20 h post-exposure. A significant increase in percent PMNs (10.7% increase per 10 $\mu\text{g}/\text{m}^3$ coarse CAPs) was observed in BAL fluid 20 h post-exposure. Percent monocytes in BL fluid were slightly decreased at 20 h post-exposure (2.0% decrease per 10 $\mu\text{g}/\text{m}^3$ CAPs; $p = 0.05$). Total protein in BAL fluid was also observed to decrease following CAPs exposure (1.8% decrease per 10 $\mu\text{g}/\text{m}^3$ CAPs). Markers of inflammation in BAL and BL fluids including IL-6, IL-8, and PGE ₂ were not affected by exposure to coarse CAPs. |
| Reference: Huang et al. (2003, 087377) Subjects: 38 healthy adults Gender: 36 M/2 F Age: Avg 26.2 \pm 0.7 yrs | Fine CAPs (Chapel Hill, NC) Concentration: 23.1-311.1 $\mu\text{g}/\text{m}^3$ | Subjects exposed to CAPs (n = 30) or filtered air (n = 8) for 2 h with intermittent exercise (subjects did not serve as their own controls). Component data of CAPs was available for 37 of the 38 subjects. Time to analysis: 18 h after exposure. | The increase in bronchoalveolar lavage fluid neutrophils observed by Ghio et al. (2000, 012140) following exposure to fine CAPs was shown to be associated with iron, selenium, and sulfate content of the CAPs. |

| Reference: Kongerud et al. (2006, 156656) Subjects: 17 asthmatic adults, 46 healthy adults Gender: Asthmatics- 6 M/11 F, Healthy- 24 M/22 F Age: Asthmatics: avg 23 yrs, Healthy: avg 26 yrs | DEP NIST 1650, heavy duty diesel engine Concentration: Untreated and treated with 0.1 ppm ozone (48 h); 300 μg per nostril | DEP (with and without ozone pre-treatment) were intranasally instilled, using the saline vehicle as control. Subjects did not serve as their own controls (not a crossover design). Time to analysis: 4 and 96 h post-instillation. | Exposure to DEP was not observed to alter markers of inflammation in nasal lavage fluid (e.g., cell counts, IL-8, IL-6) at 4 or 96 h post-instillation. |
| Reference: Larsson et al. (2007, 189320) Subjects: 16 healthy adults Gender: 10 M/6 F Age: 19-59 yrs | Traffic particles (road tunnel) Particle Size: PM _{2.5} , PM ₁₀ ; PM _{2.5} mass constituted ~ 36% of PM ₁₀ mass Particle Number/Count: 20-1,000 nm: $1.1 \times 10^5/\text{cm}^3$, < 100 nm: $0.85 \times 10^5/\text{cm}^3$ Concentration: PM _{2.5} - 46-81 $\mu\text{g}/\text{m}^3$; PM ₁₀ - 130-206 $\mu\text{g}/\text{m}^3$ | Exposures were conducted for 2 h with intermittent exercise in a room adjacent to a busy road tunnel. Study used a randomized crossover design with each subject also exposed to normal air (control). Exposures were separated by 3-10wks. No exposures to filtered air were conducted. Other traffic emissions measured: NO (874 $\mu\text{g}/\text{m}^3$), NO ₂ (230 $\mu\text{g}/\text{m}^3$), CO (5.8 $\mu\text{g}/\text{m}^3$ reported, likely 5.8 mg/m ³). Time to analysis: 14 h post-exposure. | An increase in bronchoalveolar lavage fluid cell number, lymphocytes, and alveolar macrophages were observed 14 h after road tunnel exposure relative to control. Traffic particulate exposure was not shown to effect cytokine or adhesion molecule expression in bronchial tissues. Respiratory symptoms were reported to increase during exposure to road tunnel air relative to pre-exposure symptom ratings. Exposure to road tunnel air was not shown to affect lung function. |
| Reference: Mudway et al. (2004, 180208) Subjects: 25 healthy adults Gender: 16 M/9 F Age: 19-42 yrs | DE Idling 1991 Volvo diesel engine (TD45, 4.5 L, 4 cylinders, 680 rpm) Concentration: PM ₁₀ 100 $\mu\text{g}/\text{m}^3$ | Subjects exposed to DE and filtered air for 2 h with intermittent exercise (15-min periods) in a randomized crossover design. Exposures were separated by at least 3 wks. Other diesel emissions measured: NO ₂ (0.2 ppm), NO (0.6 ppm), CO (1.7 ppm), total hydrocarbons (1.4 ppm), formaldehyde (43.5 $\mu\text{g}/\text{m}^3$). Time to analysis: 1 h after the start of exposure, immediately following exposure, and 6 h post-exposure. | DE caused mild throat irritation in some subjects and a significant increase in airways resistance (Raw) during or immediately following exposure. No changes in FEV ₁ or FVC were observed following exposure to diesel. Neutrophil numbers in the bronchial airways tended to increase following exposure to DE, however, this increase was highly variable between subjects and did not reach statistical significance. Exposure to DE did not affect levels of SOD or malondialdehyde in the airways. An increase in levels of ascorbate and GSH in nasal lavage fluid was observed 6 h following exposure to DE. |
| Reference: Pietropaoli et al. (2004, 156025) Subjects: 16 asthmatic adults, 40 healthy adults Gender: Asthmatic: 8 M/8 F, Healthy: 20 M/20 F Age: 18-40 yrs | Ultrafine elemental carbon Particle Size: CMD ~ 25 nm Particle Number/Count: 10 $\mu\text{g}/\text{m}^3$: $\sim 2.0 \times 10^9/\text{cm}^3$; 25 $\mu\text{g}/\text{m}^3$: $\sim 7.0 \times 10^9/\text{cm}^3$; 50 $\mu\text{g}/\text{m}^3$: $\sim 10.8 \times 10^9/\text{cm}^3$ Concentration: 10, 25, and 50 $\mu\text{g}/\text{m}^3$ | Study conducted using a randomized crossover design with 2-h exposures. Asthmatics (n = 16) exposed to filtered air and 10 $\mu\text{g}/\text{m}^3$. 12 healthy adults exposed to filtered air and 10 $\mu\text{g}/\text{m}^3$ at rest; 12 healthy adults exposed to filtered air, 10 and 25 $\mu\text{g}/\text{m}^3$ with intermittent exercise; 16 healthy adults exposed to filtered air and 50 $\mu\text{g}/\text{m}^3$ with intermittent exercise. Exposures were conducted via mouthpiece. Time to analysis: Immediately following exposure as well as 3.5, 21, and 45 h post-exposure. | No PM-induced changes in eNO or cell counts, IL-6, or IL-8 in induced sputum were observed in any of the protocols 21 h following exposure. Ultrafine carbon was not observed to increase respiratory symptoms in any of the study protocols. Healthy adults experienced an ultrafine PM-induced reduction in maximal mid-expiratory flow and CO diffusing capacity relative to filtered air 21 h following exposure. |
| Reference: Pourazar et al. (2005, 088305) Subjects: 15 healthy adults Gender: 11 M/4 F Age: 21-28 yrs | DE Idling Volvo diesel engine Particle Number/Count: $4.3 \times 10^6/\text{cm}^3$ Concentration: PM ₁₀ 300 $\mu\text{g}/\text{m}^3$ | Subjects exposed to DE and filtered air for 1 h with intermittent exercise (randomized crossover study design). Other diesel emissions measured: NO ₂ (1.6 ppm), NO (4.5 ppm), CO (7.5 ppm), total hydrocarbons (4.3 ppm), formaldehyde (0.26 mg/m ³). Time to analysis: 6 h post-exposure. | Exposure to DE significantly increased nuclear translocation of NF- κ B, AP-1, phosphorylated p38, and phosphorylated JNK in bronchial epithelium 6 h post-exposure. |
| Reference: Pourazar et al. (2008, 156884) Subjects: 15 healthy adults Gender: 11 M/4 F Age: 21-28 yrs | DE Idling Volvo diesel engine Particle Number/Count: $4.3 \times 10^6/\text{cm}^3$ Concentration: PM ₁₀ 300 $\mu\text{g}/\text{m}^3$ | Subjects exposed to DE and filtered air for 1 h with intermittent exercise (randomized crossover study design). Other diesel emissions measured: NO ₂ (1.6 ppm), NO (4.5 ppm), CO (7.5 ppm), total hydrocarbons (4.3 ppm), formaldehyde (0.26 mg/m ³). Time to analysis: 6 h post-exposure. | Exposure to DE observed to enhance epidermal growth factor receptor (EGFR) expression in bronchial epithelium 6 h post-exposure. |
| Reference: Riechelmann et al. (2004, 180120) Subjects: 30 healthy adults Gender: 11 M/19 F Age: 22-32 yrs | Urban dust NIST SRM 1649a Concentration: 150, 500 $\mu\text{g}/\text{m}^3$ | Subjects exposed to both concentrations of urban dust (nose only exposure system) as well as filtered air for 3h at rest in a randomized crossover design. Exposures were separated by at least 1 wk. Time to analysis: 30 min, 8 h, and 24 h post-exposure. | An increase in nasal secretion (nasal cytology) of IL-6 and IL-8 were observed 24 h after exposure to 500 $\mu\text{g}/\text{m}^3$ urban dust. |

| Reference: Samet et al. (2007, 156940) Subjects: Ultrafine CAPs: 20 healthy adults, Coarse CAPs: 14 healthy adults Gender: Ultrafine CAPs: 11 M/9 F, Coarse CAPs: 8 M/6 F Age: 18-35 yrs | CAPs (Chapel Hill, NC) Particle Size: Ultrafine: $0.049 \pm 0.009 \mu\text{m}$, Coarse: $3.59 \pm 0.58 \mu\text{m}$ Concentration: Ultrafine: $47.0 \pm 20.2 \mu\text{g}/\text{m}^3$, Coarse: $89.0 \pm 49.5 \mu\text{g}/\text{m}^3$ | Preliminary report comparing effects of controlled exposures to coarse, fine, and ultrafine CAPs among healthy adults (3 separate studies). A randomized crossover design was used in evaluating effects of coarse CAPs (n=14) and ultrafine CAPs (n=20) relative to filtered air following of 2-h exposures with intermittent exercise. Results compared with previous study of controlled exposure to fine CAPs (Chapel Hill, NC) where subjects did not serve as their own controls (Ghio et al., 2000, 012140) Time to analysis: 0-20 h post-exposure. | As was shown with fine CAPs, exposure to coarse CAPs increased the percentage of neutrophils in bronchoalveolar lavage fluid 20 h following exposure. Unlike fine CAPs, coarse CAPs did not increase the percent of monocytes in bronchoalveolar lavage fluid. Ultrafine CAPs were not shown to affect any markers of pulmonary inflammation in bronchoalveolar lavage fluid 18 h after exposure. No CAPs-induced changes in lung function were observed. |
| Reference: Samet et al. (2009, 191913) Subjects: 19 healthy adults Gender: 10 M/9 F Age: 18-35 yrs | Ultrafine CAPs (Chapel Hill, NC) Particle Size: $< 0.16 \mu\text{m}$ Particle Number/Count: $120,662 \pm 48,232$ particles/ cm^3 Concentration: $49.8 \pm 20 \mu\text{g}/\text{m}^3$ | Subjects exposed for 2 h with intermittent 15 periods of exercise to UF CAPs and filtered air using a randomized crossover study design. Time to analysis: Immediately following exposure and 1 and 18 h post-exposure. | No effect of UF CAPs observed on pulmonary function immediately following exposure or 18 h post-exposure. IL-8 in BAL fluid was observed to increase with UF CAPs 18 h post-exposure. UF CAPs was not shown to alter any other inflammatory markers in BAL fluid. |
| Reference: Schaumann et al. (2004, 087966) Subjects: 12 healthy adults Gender: 4 M/8 F Age: Avg 27 ± 2.5 yrs | Fine PM Collected (filter) from industrialized and non-industrialized areas in Germany Concentration: $100 \mu\text{g}$ per subject | Bronchoscopic instillation of particles collected from both areas was conducted in contralateral lung segments for each subject. Time to analysis: 24 h post-instillation. | Particles collected from the industrialized area (transition metal-rich) increased the percentage of monocytes and oxidant radical generation in bronchoalveolar lavage fluid 24 h after exposure compared with PM containing less metal. |
| Reference: Stenfors et al. (2004, 157009) Subjects: 15 asthmatic adults, 25 healthy adults Gender: Asthmatic: 10 M/5 F, Healthy: 16 M/9 F Age: Asthmatic: 22-52 yrs, Healthy: 19-42 yrs | DE Volvo diesel engine Concentration: PM_{10} $108 \mu\text{g}/\text{m}^3$ | Subjects were exposed for 2 h with intermittent exercise to DE and filtered air using a randomized crossover study design. Other diesel emissions measured: NO_2 (0.7 ppm). Time to analysis: 1 h after the start of exposure, immediately following exposure, and 6 h post-exposure. | DE was observed to increase neutrophilia and IL-8 in bronchial lavage fluid among healthy subjects 6 h after exposure. Among asthmatic subjects, exposure to DE did not cause an increase in inflammatory markers. No diesel-induced change in pulmonary function was observed during or immediately following exposure. |
| Reference: Tunnickliffe et al. (2003, 088744) Subjects: 12 asthmatic adults, 12 healthy adults Gender: Asthmatics: 7 M/5 F, Healthy: 5 M/7 F Age: Asthmatics: avg 35.7 yrs, Healthy: avg 34.5 yrs | Aerosols of ammonium bisulfate and sulfuric acid Particle Size: MMD $0.3 \mu\text{m}$ Concentration: 200, 2,000 $\mu\text{g}/\text{m}^3$ | Subjects were exposed for 1 h at rest to ammonium bisulfate (low and high concentrations), sulfuric acid (low and high concentrations) and filtered air in a randomized crossover design. Exposures were separated by at least 2 wks and were conducted using a head dome exposure system. Time to analysis: Immediately following exposure as well as 5.5-6 h post-exposure. | Neither ammonium bisulfate nor aerosolized sulfuric acid were not observed to affect lung function or respiratory systems following exposures to 200 or 2,000 $\mu\text{g}/\text{m}^3$ among healthy or asthmatic adults. Exposures to ammonium bisulfate at both concentrations resulted in a significant increase in eNO in the asthmatic subjects. |

Annex D. Toxicological Studies

Table D-1. Cardiovascular effects.

| Study | Pollutant | Exposure | Effects |
|---|---|--|--|
| Reference: Anselme et al. (2007, 097084) Species: Rat Gender: Male Strain: Wistar Age: Adult Weight: 200-225g | DE: monocylinder Diesel engine using Euro 4 ELF 85A reference gasoline Particle Size: DE: 10-650 nm (85 nm mean mobility diameter) | Route: Whole-body Inhalation Dose/Concentration: DE: 0.5 mg/m ³ ; Other emissions measured: non-methane hydrocarbons (7.7 ppm), NO ₂ (1.1 ppm), CO (4.3 ppm) Time to Analysis: Experiments started 3 months after L coronary artery ligation. ECG started at t0 and the DE exposure at t30 min for a 3h period; ventricular premature beats (VPBs) and RMSSD calculated every 30 min during clean room air exhaust and PE periods. Early (t210-300 min) and late (t480-540 min) PE were analyzed. | Immediate decrease in RMSSD was observed in both healthy and CHF rats PE. Immediate increase in VPBs observed in CHF rats only; which lasted 4-5h after exposure ceased. Whereas HRV progressively returned to baseline values within 2.5 h post-exposure (PE), the proarrhythmic effect persisted as late as 5 h PE termination in CHF rats |
| Reference: Bagate et al. (2004, 055638) Species: Rat Gender: Male Strain: SH Age: 13-15wks | LPS and EHC-93 (PM): Urban Air collected at the Health Effects Institute Ottawa, Canada Particle Size: EHC-93: 0.8-0.4 µm (mean) (range: < 3 µm) | Route: IT Instillation Dose/Concentration: PM: 10 mg/kg of bw; LPS: 350 EU/animal Time to Analysis: Sacrificed 4 or 24 h post-instillation | PM and LPS elicited a significant increase in receptor-dependent vasorelaxation of the aorta compared to saline-instilled rats. |
| Reference: Bagate et al. (2004, 055638) Species: Rat Gender: Male Strain: SH Age: 13-15wks | EHC-93 (PM), CB-V or CB-Fe, LPS Particle Size: EHC-93: 0.8-0.4 µm (mean) (range: < 3 µm) | Route: Aortic Suspension Fluid Dose/Concentration: Cumulative concentrations of EHC-93, CB-V and CB-Fe (10, 25, 50, 75, 100 µg/mL) CB 1.5-2.0 nm (mean) (range < 5 µm) Time to Analysis: Immediately post-exposure of aortic rings to cumulative concentrations of EHC-93, CB-V, CB-Fe and LPS. | CB-V particles induced more relaxation than CB-Fe particles or EHC-93 in a dose-dependent manner. PM and LPS had an acute transient effect on the receptor dependent vasorelaxation. PM and LPS attenuated ACh-elicited vasocontraction in denuded aortic rings (DARs). |

HERO is a database of scientific literature used by U.S. EPA in the process of developing science assessments such as the ^{Integrated} Science Assessments (ISA) and the Integrated Risk Information System (IRIS).

| Study | Pollutant | Exposure | Effects |
|---|--|---|--|
| Reference: Bagate et al. (2004, 055638) Species: Rat Gender: Male Strain: Wistar Kyoto Age: 13-15wks | EHC-93 (PM): Urban Air collected at the Health Effects Institute Ottawa, Canada. EHC-93 filtrate (PMF) Zn ²⁺ and Cu ²⁺ particles (10,000 and 845 µg PM respectively) Particle Size: PM: 4.6 µm (GSD = 3.2) | Route: In Vitro Dose/Concentration: PM Suspensions: 10-100 µg/mL; CuSO ₄ /ZnSO ₄ 1-100 µmol; Phe 2 µm; arbacol: 10 µm Time to Analysis: Measured immediately after maximum response for each cumulative dose was achieved. | PM-Induced Contraction: No effect of suspension or filtrate seen on resting tension of aorta and SMRA. PM- and Metal-Induced Vasorelaxation: Cumulative concentrations (10-100 µg/mL) of PM suspension and its water soluble components (PMF) elicited dose-dependent relaxation in aorta. Relaxation induced by particle suspension was higher than relaxation induced by free filtrate. The difference was significant at 100 µg/mL. In SMRA, vasorelaxation similar to aorta's was observed, and the activity of the particle suspension was stronger than the filtrate, with the difference being significant starting at 30 µg/mL. Both Zn ²⁺ and Cu ²⁺ in sulfate salts (10-100 µmol) induced relaxation in pre-contracted aortic rings, with Cu ²⁺ having a greater effect than Zn ²⁺ at the same concentration. Ions didn't affect ACh relaxation. Effect of PM on α-Adrenergic Contraction: Phenylephrine-induced dose-response contraction, starting at 1µM with max at 100 µmol. Pre-treatment of SMRA did not change the phenylephrine-induced contraction. |
| Reference: Bagate et al. (2006, 097608) Species: Rat Gender: Male Strain: Wistar Kyoto (WKY) and SH Age: 13-15wks | EHC-93 (PM) EHC-93 (Filtrate) Cu ²⁺ and Zn ²⁺ solutions Particle Size: PM: 4.6 µm (GSD = 3.2) | Route: In Vitro Dose/Concentration: PM and PMF Suspensions: 10-100 µg/mL; CuSO ₄ or ZnSO ₄ : 10-100 µmol; Phenylephrine: 2 µm; Carbacol: 10 µm Time to Analysis: Responses evaluated at maximum of each dose-response. | PM and its soluble components elicited endothelium-independent vasodilation in rat aorta rings. This response is a result of the activation of sGC since its inhibition by NS2028 practically eliminated relaxation. PM suspensions stimulated cGMP production in purified isolated sGC. Neither receptor nor their signaling pathways played a significant role in the direct relaxation by PM or metals. Vasodilation responses were significantly higher in SH than WKY control rats. |
| Reference: Bagate et al. (2006, 096157) Species: Rat Gender: Male Strain: SH/NHsd Age: 11-12 wks Weight: 250-350g | EHC-93 (PM): Urban Air collected at the Health Effects Institute Ottawa, Canada. EHC-93 (Filtrate), Zinc (in PM), LPS Particle Size: PM: 4.6 µm (GSD = 3.2) | Route: IT Instillation Dose/Concentration: PM: 10 mg/kg of bw; LPS: 350 EU/animal (0.5 mL) Time to Analysis: 4h post-exposure | Effect of Pretreatment on Baseline parameters of Isolated Perfused Heart: After PM exposure a slight increase of baseline coronary flow (CF) and heart rate (HR) was noted. In contrast, a significant decrease of left developing ventricular pressure (LDVP) was observed in SH. LPS also elicited a non-significant decrease in LDVP. Effect of Pretreatment and Ischemia on Cardiac Function: When SH rats were pretreated with PM or LPS the isolated heart had a reduced ability to recover to baseline levels after occlusion, in comparison with saline treated rats. After occlusion was released CF went back to baseline values. Saline and LPS treated rats, showed a gradual decrease in CF noted during the reperfusion period. Isolated hearts from PM-exposed SH showed a complete restoration of CF and no gradual decrease. The increase of Zn2+ elicited a rapid decrease of LDVP and HR. The impairment of cardiac function measured by LDVP and HR started immediately upon Zn2+ infusion and remained the same during the perfusion period (no Zn2+ was present in the perfusate). |
| Reference: Bagate et al. (2006, 096157) Species: Rat Strain: H9c2 (EACC), cardiomyocyte cells | EHC-93 (PM) Filtrate: Urban Air collected at the Health Effects Institute Ottawa, Canada, ZnSO ₄ Particle Size: PM: 4.6 µm (GSD = 3.2); Carbon Particles: 44nm | Route: In Vitro Dose/Concentration: PM: 1, 50, 100 µg/mL; ZnSO ₄ : 50 µmol Time to Analysis: 30min incubation | Effect of EHC-93 filtrate on Ca2+ Uptake in Cardiomyocytes: Both PMF and Zn2+ inhibited ATP or ionophore-stimulated Ca2+ influx in cardiomyocytes. |

| Study | Pollutant | Exposure | Effects |
|---|---|--|--|
| Reference: Bartoli et al. (2009, 156256) Species: Dog Gender: Female Strain: Mixed breed Age: 2-12yrs Weight: Average: 15.7kg, Range: 13.6-18.2kg | CAPs (Boston; Harvard Ambient Particle Concentrator) Particle Size: Diameter: 0.15-2.5 μm | Route: Permanent Tracheostomy Dose/Concentration: Concentration range and mean: CAPs: 94.1-1557(358.1 \pm 306.7) $\mu\text{g}/\text{m}^3$, BC: 1.3-32(7.5 \pm 6.1) $\mu\text{g}/\text{m}^3$, Particle count: 3000-69300(18230 \pm 13.151articles/ cm^3) Time to Analysis: Preanesthetized. Tracheostomy. 5h exposures separated by minimum 1wk. Prazosin administered in 8 of 13 dogs 30-60min before exposure. 55 exposure days. | CAPs significantly increased SBP, DBP, mean arterial pressure, HR and rate-pressure product. Prazosin (α -adrenergic antagonist) decreased these CAPs-induced effects. CAPs mass, BC, particle number concentrations were positively and significantly associated with each of the cardiovascular parameters except for pulse pressure. |
| Reference: Bartoli et al. (2009, 179904) Species: Dog Gender: Female Strain: Mixed breed Age: Adult Weight: 14-18kg | CAPs (Boston; Harvard Ambient Particle Concentration) Particle Size: Diameter: \approx 2.5 μm | Route: Permanent Tracheostomy Dose/Concentration: Concentration range and mean: CAPs: 94.1-1556.8 (349 \pm 282.6) $\mu\text{g}/\text{m}^3$, BC: 1.3-32 (7.5 \pm 5.6) $\mu\text{g}/\text{m}^3$, Particle number: 3000-69300 (20381 \pm 13075) $\mu\text{g}/\text{m}^3$ Time to Analysis: Tracheostomy. Minimum 3wk recovery. Acclimatized. Exposed 5h. 2 5min occlusions of LAD coronary artery separated by 20min rest. Exposure days separated by 1wk minimum. | During coronary artery occlusion, CAPs exposure reduced myocardial blood flow and increased coronary vascular resistance, SBP and DBP. CAPs effects were greater in ischemic tissue than nonischemic. Increases in CAPs mass, particle number and BC concentrations were significantly associated with decreased myocardial blood flow and increased coronary vascular resistance. |
| Reference: Campen et al. (2005, 083977) Species: Mouse Gender: Male Strain: C57BL/6J and Apo E ⁻ Age: 10-12wks | High Whole DE (HWDE); Low Whole DE (LWDE); High PM Filtered (HPMF); Low PM Filtered (LPMF) Particle Size: NR | Route: Whole-body Inhalation Chambers and Ex-vivo Exposures (isolated, pressurized septal coronary arteries) Dose/Concentration: HWDE: PM = 3.6 mg/m^3 ; NO _x = 102 ppm LWDE: PM = 0.512 mg/m^3 ; NO _x = 19 ppm; PM = 0.770 mg/m^3 ; NO _x = 105 ppm LPMF: PM = 0.006 mg/m^3 ; NO _x = 26 ppm Time to Analysis: Whole-body Exposures: DE or PFDE for 6h/day for 3 days, euthanized at the end of last exposure. Coronary Vessels Exposure: PSS bubbled with DE to expose coronary vessels to the soluble contents of DE. Analysis occurred immediately post exposure. | Whole-body Exposure on ApoE⁻: During DE exposure, ApoE ⁻ mice HR consistently decreased during high concentration exposures, compared to the C57BL/6J strain. Coronary Vascular Effects on ApoE⁻: DE had no significant effects on the resting myogenic tone of isolated septal coronary arteries. Control coronary arteries showed constrictive responses to ET-1 and dilatory responses to SNP. DE exposed PSS vessels responses to ET-1 enhanced compared to control. SNP-induced dilation blunted in vessels resting in diesel-exposed saline. |
| Reference: Campen et al. (2003, 055626) Species: Rat Gender: Male and Female Strain: SH Age: 4 m | DE: generated by either of two Cummins (2000 model) 5.9-L ISB turbo engines fueled by Number 2 Diesel Certification Fuel. Particle Size: 0.1-0.2 μm aerodynamic diameter | Route: Whole-body exposure Dose/Concentration: 0, 30, 100, 300, 1000 $\mu\text{g}/\text{m}^3$ Time to Analysis: 6 h/day for 7 days; ECG measurements taken 4 days post-exposure. | HR: Significantly higher in exposed animals and not concentration-dependent. More substantial results seen in male rats. ECG: The PQ interval was significantly prolonged among exposed animals in a concentration-dependent manner. |
| Reference: Campen et al. (2006, 096879) Species: Mouse Gender: Male Strain: ApoE ⁻ Age: 10wks | Road dust from paved surfaces (Reno, NV) Gasoline engine emissions, containing PM, NO _x , CO and HC Particle Size: Road dust: 1.6 μm (Standard Deviation 2.0) Gasoline engine emissions: Average particle diameter of 15 nm | Route: Whole-body inhalation Dose/Concentration: Road dust: 0.5 and 3.5 mg/m^3 ; Gasoline engine emissions: 5 to 60 $\mu\text{g}/\text{m}^3$ (at dilutions of 10:1, 15:1, and 90:1) Mean concentrations of PM: 61 $\mu\text{g}/\text{m}^3$; NO _x : 18.8 ppm; CO: 80 ppm. Time to Analysis: 6h/d for 3d. Sacrificed 18h post-exposure. | ET-1: Gasoline exhaust significantly upregulated ET-1 in a dose-dependent manner. ET-1 increased levels in the PM filtered group and decreased in the low levels of road dust. ECG: HR consistently decreased from beginning to end of exposure in all groups. No significant HR effects on road dust or gasoline exposure was observed. No significant effects on P-wave, PQ-interval, QRS-interval, or QT-interval were observed in either treatment. T-wave: Mice exposed to whole gasoline exhaust displayed significant increases in T-wave morphology from the beginning of exposures; this effect was consistent on all exposure days. |

| Study | Pollutant | Exposure | Effects |
|--|---|---|--|
| Reference: Cascio et al. (1987, 007583) Species: Mouse Gender: Male Strain: ICR Age: 6-10wks | UFPM: Ultra fine PM, EPA Chapel Hill, NC Particle Size: < 0.1 μm | Route: IT Instillation Dose/Concentration: 100 μg in 100 μl Time to Analysis: 24h post-exposure (single exposure) | UFPM exposure double the size of myocardial infarction attendant to an episode of ischemia and reperfusion while increasing post ischemic oxidant stress. UFPM alters endothelium-dependent/independent regulation of systemic vascular tone; increases platelet number, plasma fibrinogen, and soluble P-selectin levels; reduces bleeding time. |
| Reference: Chang et al. (2007, 155720) Species: Rat Gender: Male Strain: SH Age: 60d | UfCB: Ultra fine carbon black sulfate $\text{Fe}_2(\text{SO}_4)_3$ Nickel sulfate NiSO_4 Particle Size: UfCB | Route: IT Instillation Dose/Concentration: UfCB: 415 and 830 μg Ferric Sulfate: 105 and 210 μg Nickel Sulfate: 263 and 526 μg Combined UfCB and ferric sulfate: 830 μg UfCB + 105 μg Ferric Sulfate Combined UfCB with Nickel Sulfate: 830 μg UfCB + 263 μg Nickel Sulfate Time to Analysis: Single dose, radiotelemetry readings recorded for 72h post exposure. | Both high/low-dose UfCB decreased ANN (normal-to-normal intervals) slightly around the 30th hour, concurrent increases of LnSDNN. LnRMSSD returned to baseline levels after small initial increases. Minor effects observed after low-dose Fe and Ni instillation; biphasic changes occurred after high-dose instillations. Combined exposures of UfCB and either Fe or Ni resulted in HRV trends different from values estimated from individual-component effects. |
| Reference: Chang et al. (2007, 155720) Species: Rat Gender: Male Strain: SH Age: 10wks | CAPs: collected during a dust storm from Chung-Li, Taipei Particle Size: $\text{PM}_{2.5}$ | Route: Nose-only Inhalation Dose/Concentration: 315.55 $\mu\text{g}/\text{m}^3$ Time to Analysis: 6h | A linear mixed-effects model revealed sigmoid increases in HR and a sigmoid decrease of QAI during exposure, after an initial incubation period. |
| Reference: Chang et al. (2004, 055637) Species: Rat Gender: Male Strain: SH Age: 60d | CAPs collected in Chung-Li, Taipei (spring and summer periods) Particle Size: $\text{PM}_{2.5}$ | Route: Nose-only Inhalation Dose/Concentration: Spring exposure: $202.0 \pm 68.8 \mu\text{g}/\text{m}^3$; Mean number concentration: 2.30×10^5 particles/ cm^3 (range: $7.12 \times 10^3 - 8.26 \times 10^5$) Summer exposure: $141.0 \pm 54.9 \mu\text{g}/\text{m}^3$; Mean number concentration: 2.78×10^5 particles/ cm^3 (range: $7.76 \times 10^3 - 8.87 \times 10^5$) Time to Analysis: 4d of spring exposure and 6d of summer exposure for 5h each exposure. Parameters measured throughout duration of exposures. | During spring exposures, the maximum increase of heart rate (HR) and blood pressure (BP) were 51.6 bpm and 8.5 mmHg respectively. The maximum decrease of QAI (measures cardiac contractility) noted at the same time was 1.6 ms. Similar pattern was observed during summer exposure, however., the responses were less prominent. |
| Reference: Chang, et al. (2005, 097776) Species: Rat Gender: Male Strain: SH Weight: 200g | CAPs collected in Chung-Li, Taipei Particle Size: $\text{PM}_{2.5}$ (0.1-2.5 μm) | Route: Nose-only Inhalation Dose/Concentration: $202.0 \pm 68.8 \mu\text{g}/\text{m}^3$ Time to Analysis: 5h/d for 4d | During the inhalation stage, crude effects of both LnSDNN and LnRMSSD for exposure and control groups decreased from the baseline values. Immediately after the experiments, both LnSDNN and LnRMSSD decreased due to stresses produced by release from the exposure system, then returned to the baseline values. |
| Reference: Chauhan et al. (2005, 155722) Tumor Cell Line: A549 derived from alveolar type II epithelial cells | SRM-1879 (SiO_2) and SRM-154b (TiO_2) from the NIST EHC-93 from Ontario, Canada (EHCsol, EHCinsol) Particle Size: EHC-93 median physical diameter: 0.4 μm ; TiO_2 and SiO_2 particle size distribution: 0.3-0.6 μm | Route: Cell Culture Dose/Concentration: 0, 1, 4, and 8 mg EHC total equivalent per 5 mL Time to Analysis: Culture medium was removed from flasks and replaced w/ 5 mL of the particle suspension media. Plates were incubated for 24h. After 24h cell culture supernatants were collected and analyzed. | The decreased expression of preproET-1 in A549 cells suggests that epithelial cells may not be the source of higher pulmonary ET-1 spillover in the circulation measured in vivo in response to inhaled urban particles. However, higher levels ECE-1 in A549 post-exposure to particles suggests an increased ability to process bigET-1 into mature ET-1 peptide, while increased receptor expression implies responsiveness. The increased release of IL-8 and VEGF by epithelial cells in response to particles could possibly up regulate ET-1 production in the adjacent pulmonary capillary endothelial cells, with concomitant increased ET-1 spillover in the systemic circulation. |

| Reference: Chen et al. (2005, 087218) Species: Mouse Strain: Normal (C57) and ApoE ^{-/-} | CAPs (NYU, NY) Particle Size: PM _{2.5} | Route: Whole-body Inhalation Dose/Concentration: 10 x ambient concentrations 19.7 µg/m ³ average concentration over 5 months (daily average exposure concentration was 110 µg/m ³) Time to Analysis: 6h/d, 5 d/wk, for 5m. Parameters measured continuously throughout. | Significant decreasing patterns of HR, body temperature, and physical activity for ApoE ^{-/-} mice, with nonsignificant changes for C57 mice. SDNN and RMSSD in the late afternoon and overnight for ApoE ^{-/-} mice showed a gradual increase for the first 6 weeks, a decline for about 12 more weeks, and a slight turn upward at the end of the study period. For C57 mice, there were no chronic effect changes in SDNN or RMSSD in the late afternoon, and a slight increase after 6 weeks for the overnight period. |
| Reference: Chen LC and Nadziejkov C, (2005, 087219) Species: Mouse Strain: Normal (C57), ApoE ^{-/-} , Age: 26-28wks (C57), 39-41wks (ApoE ^{-/-}), and 18-20wks (LDLr ^{-/-} [DK]) | CAPs (NYU, NY) Particle Size: PM _{2.5} | Route: Whole-body Inhalation Dose/Concentration: Mean exposure concentration: 110 µg/m ³ Time to Analysis: 6h/d, 5d/wk for up to 5m. Sacrificed 3 to 6d after last exposure. | All DK mice developed extensive lesions in the aortic sinus regions. In male DK mice, the lesion areas appeared to be enhanced by CAPs exposure. Plaque cellularity was increased, but there were no CAPs-associated changes in the lipid content. ApoE ^{-/-} and DK mice showed prominent areas of severe atherosclerosis. Quantitative measurements showed that CAPs increased the percentage of aortic intimal surface covered by grossly discernible atherosclerotic lesion. |
| Reference: Corey LM et al. (2006, 156366) Species: Mouse Gender: Male Strain: ApoE ^{-/-} Age: 11-12m Weight: 32.84g (avg) | PM collected November – March between 1996-1999(Seattle, WA) Silica (U.S. Silica Company, Berkeley Springs, WV) Particle Size: PM _{2.5} | Route: Nasal Instillation Dose/Concentration: PM: 1.5 mg/kg; Saline: 50ul; Silica: Min-u-Sil 5 in 50 ul saline Time to Analysis: Mice monitored for 1d baseline prior to and for 4d following exposure. | After an initial increase in both HR and activity in all groups, there was delayed bradycardia with no change in activity of the animals in the PM and silica exposed groups. In addition, with PM and silica exposure, there was a decrease in HRV parameters. |
| Reference: Cozzi et al. (2006, 091380) Species: Mouse Strain: ICR Age: 6-10wks | Ultrafine PM (collected continuously over 7 day periods in Oct 2002 in Chapel Hill, NC) Particle Size: < 150nm | Route: IT Instillation Dose/Concentration: 100 µg of PM in vehicle Time to Analysis: 24h post-exposure | Ischemia-Reperfusion: PM exposure doubled the relative size of myocardial infarction compared with the vehicle control. No difference was observed in the percentage of the vehicle at the risk of ischemia. PM exposure increased the level of oxidative stress in the myocardium after I-R. The density of neutrophils in the reperfused myocardium was increased by PM exposure, but differences in the numbers of blood leukocytes, expression of adhesion molecules on circulating neutrophils, and activation state of circulating neutrophils, 24 h after PM exposure, could not be correlated to the increase I-R injury observed. Isolated Aortas: Aortas isolated from PM-exposed animals exhibited a reduced endothelium-dependent relaxation response to ACh. |
| Reference: Dvonch JT et al. (2004, 055741) Species: Rat Gender: Male Strain: Brown Norway | CAPs, Detroit, MI Particle Size: PM _{2.5} | Route: Whole-body Inhalation Chamber Dose/Concentration: Average concentration 354 µg/m ³ Time to Analysis: 8h/d for 3 consecutive days; plasma samples collected 24h post-exposure. | Plasma concentrations of asymmetric dimethylarginine (ADMA) were significantly elevated in rats exposed to CAPs versus filtered air. |

| Reference: Elder et al. (2004, 055642) Species: Rat Gender: Male Strain: Fischer 344 and SH Age: 23m (Fischer); 11-14m (SH) Weight: NR | UFP - Ultrafine carbon particles; LPS (Sigma) Particle Size: UFP: 36nm (median size) | Route: Intraperitoneal Injection (ip) for saline and LPS Whole-body exposure for inhaled particles Dose/Concentration: Particles: 150 mg/m ³ ; LPS: 2mg/kg bw Time to Analysis: Single 6h exposure to particles. Sacrificed 24h after ip LPS exposure. | BAL fluid cells: Neither inhaled UFP nor ip LPS cause a significant increase in BAL fluid total cells or the percentage of neutrophils in either rat strain. No significant exposure-related alteration in total protein concentration or the activities of LDH and b-glucuronidase. Peripheral blood: In both rat strains ip LPS induced significant increase in the number and percentage of circulating PMNs. When combined with inhaled UFP, PMNs decreased, significantly for F-344 rats. Plasma fibrinogen increased with ip LPS in both rat strains with the magnitude of change greater in SH rats. UFP alone decreased plasma fibrinogen in SH rats. Combined UFP and LPS response was blunted, but significantly higher than controls. Hematocrit was not altered in either rat strain by any treatment. TAT complexes: With all exposure groups averaged, plasma TAT complexes in SH rats were 6.5 times higher than in F-344 rats. LPS caused an overall increase in TAT complexes for F-344 rats that was further augmented by inhaled UFP. UFP alone decreased response. In SH rats, UFP alone significant increased response and LPS decreased response. ROS in BAL cells: In F-344 rats both UFP and LPS have independent and significant effects on DCFD oxidation. Effects were in opposite directions; particles decreased ROS, LPS increased ROS. |
| Reference: Finnerty et al. (2007, 156434) Species: Mouse Gender: Male Strain: C57BL/6 Age: 9 wks Weight: 22-2g | Coal Fly Ash (U.S. EPA), Analysis: (PM _{2.5} samples) low unburned carbon (0.53 wt%), moderate levels of transition metals, including (in µg/g): Fe (30, 400), Mg (31, 200), Ti (6, 180), Mn (907), and V (108). Particle Size: 1.8 and 2.5µm | Route: IT Instillation Dose/Concentration: PM: 200 µg; PM + 10 µg LPS: 200 µg; PM + 100 µg LPS: 200 µg Time to Analysis: 18h after IT instillation | Plasma: TNF-α significantly increased in both PM+LPS10 and PM+LPS100 treatments. For plasma IL-6, all groups tended to rise with a significant increase in the PM+LPS100 group. |
| Reference: Floyd et al. (2009, 190350) Species: Mouse Gender: Male Strain: ApoE ^{-/-} Age: 20wks | CAPs: PM _{2.5} concentrated from Tuxedo, NY (April–Sept 2003) Particle Size: NR | Route: Whole-body Inhalation Dose/Concentration: Avg 120 µg/m ³ (n = 6/group) Time to Analysis: 6h/d × 5d/wk × 5m | Gene Expression: Microarray gene expression identified 395 genes downregulated and 216 genes upregulated in the aortic plaques. Ontologic analysis identified a list of functional processes associated with gene expression and included: inflammation, tissue development, cellular movement, cellular growth and proliferation, hematological system development and function, lipid metabolism, cardiovascular system function, cellular assembly and organization, and cell death. |
| Reference: Floyd et al. (2009, 190350) Species: Mouse Gender: NR Strain: ApoE ^{-/-} Age: 6wks Weight: NR | CAPs (Tuxedo, NY) (April–September 2003) (modified VACES system) Particle Size: NR | Route: Exposure Chamber Dose/Concentration: Average concentration: 120 µg/m ³ Time to Analysis: Exposed 6h/d, 5d/wk, 5m. | CAPs altered 611 genes of which 306 were significantly related to alterations in molecular pathways and associated with biological pathways. The 50 most significant biological function alterations related to CVD. Further analysis of recent literature showed that some CAPs-altered genes were the same as genes altered by CVD or unstable-human plaque gene expression. |
| Reference: Folkmann et al. (2007, 097344) Species: Mouse Gender: Female Strain: Wild type and ApoE ^{-/-} Age: 11-13wks Weight: 21g (avg) | DEP: SRM2975 (particulate fraction of exhaust from a filtering system designed for diesel-powered forklifts). Particle Size: DEP: NR | Route: Intraperitoneal Injection Dose/Concentration: 0, 50, 500, 5,000 µg DEP/kg of bw Time to Analysis: 6 or 24 h post-ip injection | The expression of inducible nitric oxide synthase (iNOS) mRNA was increased in the liver 6h post-ip injection. The level of oxidized purine bases, determined by formamido-pyrimidine DNA glycosylase sites increased significantly in the liver after 24 h in mice injected w/ 50µg/kg of bw. There was no indication of systemic inflammation determined as the serum concentration of nitric oxide and iNOS expression, and DNA damage was not increased in the aorta. |

| Reference: Furuyama et al. (2006, 097056) Species: Rat Cell Type: Heart Micro vessel Endothelial (RHMVE) Cells | OE-DEP, OE-UFP (from Urawa, Saitama, Japan) OE = Organic Extracts Particle Size: NR | Route: Cell Culture Dose/Concentration: 0, 5, 10, 25 $\mu\text{g/mL}$ of OE-DEP or OE-UFP Time to Analysis: Exposed for 0, 6, 12, 24, or 36h | The cell monolayer exposed to 10 $\mu\text{g/mL}$ OE-UFP produced a larger amount of HO-1 than cells exposed to 10 $\mu\text{g/mL}$ OE-DEP. OE-DEP and OE-UFP exposure reduced PAI-1 production by the cells but did not affect the production of thrombomodulin, tissue-type PA, or urokinase-type PA. Increased PAI-1 synthesis in response to treatment with 1ng/mL TNF- α or 0.5ng/mL TGF- β 1 was reduced by OE-DEP exposure. Suppression of PAI-1 production by OE-DEP exposure was mediated through oxidative stress and was independent of HO-1 activity. |
| Reference: Gerlofs-Nijland et al. (2009, 190353) Species: Rat Gender: Male Strain: SH Age: 12wks Weight: 200-300g | PM (Prague, Czech Republic; Duisburg, Germany; Barcelona, Spain) (Prague and Barcelona coarse PM organic extracts) Particle Size: Coarse: 2.5-10 μm , Fine: 0.2-2.5 μm | Route: IT Instillation Dose/Concentration: 7mg PM/kg body weight Time to Analysis: DTPA added to some PM samples preinstillation. Instilled with PM. Necropsy 24h postexposure. | Inflammation (LDH, protein, albumin), cytotoxicity (NAG, MPO, TNF- α), and fibrinogen were increased by PM, and were greatest in the coarse PM fraction. Metal-rich PM had greater inflammatory and cytotoxic effects, and increased fibrinogen and vWF and decreased ACE. PAH content influenced greater inflammation (including neutrophils), cytotoxicity, and fibrinogen. Generally, whole PM and coarse PM were more potent than organic extracts and fine PM, respectively. |
| Reference: Ghelfi et al. (2008, 156468) Species: Rat Strain: Sprague-Dawley Age: Adult | CAPs CPZ (Capsazepine) (Axxora LLC, San Diego, CA) Particle Size: PM _{2.5} | Route: CAPs: Inhalation via Whole-body Exposure; CPZ: IP Injection or Aerosol Dose/Concentration: CAPs: mean mass concentration: $218 \pm 23 \mu\text{g/m}^3$; CPZ: 10mg/kg (ip), 500 μmol (aerosol) Time to Analysis: Experiment 1: CPZ ip or 20min aerosol pretreatment immediately prior to CAPs exposure. Single CAPs exposure for 5h. Parameters measured immediately following exposure. Experiment 2: CPZ ip pretreatment prior to CAPs exposure. Exposed to CAPs for 5h/day for 4mths. Parameters measured throughout duration of experiment. | CPZ (ip or aerosol) decreased CAPs-induced chemiluminescence (CL), lipid thiobarbituric acid reactive substances (TBARS), and edema in the heart, indicating that blocking TRP receptors, systemically or locally, decreases heart CL. CAPs exposure led to significant decreases in HR and in the length of QT, RT, Pdur and Tpe intervals. These changes were observed immediately upon exposure, and were maintained throughout the 5h period of CAPs inhalation. Changes in cardiac rhythm and ECG morphology were prevented by CPZ. |
| Reference: Gilmour et al. (2004, 054175) Species: Rat Gender: Male Strain: Wistar (CrI: WI) BR | ufCB (Printex 90 from Frankfurt, Germany) fCB (Huber 990 from UK) Particle Size: ufCB: 114 nm (MMAD); fCB: 268 nm (MMAD). | Route: Whole-body Inhalation Dose/Concentration: ufCB: 1.66 mg/m^3 ; fCB: 1.40 mg/m^3 Time to Analysis: Single exposure for 7h. Sacrificed and samples taken at 0, 16, and 48h post-exposure. | Exposure to ultrafine, but not fine, CB particles was also associated with significant increases in the total number of blood leukocytes. Plasma fibrinogen factor VIII and vWF were unaffected by particle treatments as was plasma Trolox equivalent antioxidant status. |
| Reference: Gilmour PS et al.(2005, 087410) Species: Human Cell Types: Primary Human Monocyte Derived Macrophages (MP); Human Umbilical Vein Endothelial Cells (HUVEC); A549 cells; Human Bronchial Epithelial Cells (16HBE) | PM ₁₀ : (Carbon Black from Degussa Ltd, Frankfurt, Germany) Particle Size: PM ₁₀ | Route: Cell Culture Dose/Concentration: PM ₁₀ : 50 and 100 $\mu\text{g/mL}$ Time to Analysis: 6 and 20h | The culture media from MPs and 16HBE cells but not A549 cells, exposed to PM ₁₀ had an enhanced ability to cause clotting. H2O2 also increased clotting activity. Apoptosis was significantly increased in MPs exposed to PM ₁₀ and LPS as shown by annexin V binding. TF gene expression was enhanced in MPs exposed to PM ₁₀ and HUVEC tissue factor. tPA gene and protein expression were inhibited. |

| Reference: Gilmour et al. (2006, 156472) Species: Rat Gender: Male Strain: Wistar Kyoto Age: 12-14wks Weight: 280-340g | Zinc Sulfate (ZnSO ₄ in saline solution) Particle Size: NR | Route: IT Instillation Dose/Concentration: 131 µg/kg of bw (2 µmol/kg) Time to Analysis: 1, 4, 24, 48h | Zinc levels in plasma and tissue: At 1-24 h post-exposure, zinc plasma levels increased to nearly 20% above baseline. mRNA expression: Cardiac tissues demonstrated similar temporal increases in expressions of TF, PAI-1 and thrombomodulin mRNA, following pulmonary instillation of Zn. Cardiac histopathology: Mild and focal acute, myocardial lesions developed in a few Zn exposed rats. No changes in fibrin deposition or troponin disappearance were observed. At 24 and 48h PE to Zn, increases occurred in levels of systemic fibrinogen and the activated partial thromboplastin time. |
| Reference: Gong et al. (2007, 091155) Species: Human and Mouse Cell Type: Human Microvascular Endothelial Cells (HMEC) Strain: C57BL/6J Gender: Male (mouse) Age: 2m (mouse) | Organic DEP extract: collected from exhaust in a 4JB1-type LD, 2.74 liter, 4-cylinder Isuzu diesel engine (provided by Masaru Sagai, Tsukuba, Japan) ox-PAPC: (provided by Judith Berliner, UCLA, CA) In vivo validation: Ultrafine (ufp) and fine (fp) particulate matter Particle Size: DEP < 1 µm (diameter) | Route: Cell culture; In vivo validation via Whole-body inhalation Dose/Concentration: ox-PAPC: 10, 20, and 40 µg/mL; DEP: 5, 15, and 25 µg/mL; DEP (5 µg/mL) + ox-PAPC: 10 or 20 µg/mL In Vivo Valudation: Ufp: 3.24x10 ⁵ /cm ³ fp: 2.7x10 ⁵ /cm ³ In vivo validation: Ufp: < 0.18 µm; fp: < 2.5 µm Time to Analysis: 4h In vivo validation: Exposed to CAPs for 5h/day, 3d/wk for 8wks. Sacrificed 24h after last CAPs exposure. | Gene-expression profiling showed that both DEP extract and ox-PAPC co-regulated a large number of genes. U sinfg network analysis to identify co-expressed gene modules, led to the discovery of three modules that were highly enriched in genes that were differentially regulated by the stimuli. These modules were also enriched in synergistically co-regulated genes and pathways relevant to vascular inflammation. In vivo validation: Results were validated by demonstrating that hypercholesterolemic mice exposed to ambient ultrafine particles inhibited significant upregulation of the module genes in the liver. |
| Reference: Goto et al. (2004, 088100) Species: Rabbit Gender: Female Strains: NZW Age: NR Weight: 2.3 kg | EHC-93 (Ottawa, ON, Canada) CC: Coiloidial Carbon (obtained from Hamburg, Germany) Particle Size: EHC-93: PM ₁₀ ; CC: < 1 µm | Route: Intrabronchial Instillation Dose/Concentration: AMs incubated with EHC-93 or CC: 0.6 ml/kg EHC-93 alone: 1 mL (500 µg/ mL) CC alone: 1mL (1% CC) Time to Analysis: WBC counts measured 4 - 168h after BrdU injection. Sacrificed 7d post instillation. | Lung distribution of PM₁₀: PM-containing AMs were distributed diffusely. PM-containing AMs were more prevalent in the PM exposed animals. There was no AM-containing particle difference between the CC-exposed and EHC-93-exposed groups. Monocyte release from Bone Marrow: EHC exposure increased WBC and band cell counts from 12hours after instillation. Monocyte count was not affected. Labeled monocytes peaked more quickly after DEP exposure (12h vs 16 h for control). There was no observed change in BM monocyte pool. Cytokine release: EHC stimulation increased the release of GM-CSF, IL-6, IL-1β, TNF-α, IL-8 and MCP-1. No effect on m-CSF and MIP-1β. CC particles induced increases in IL-6 and TNF-α; other cytokine levels did not differ from control. Supernatant instillation: AM + EHC increased circulating WBC and band cell counts. Circulating monocyte counts were unaffected. AM + EHC showed a major increase in fraction and amount of monocyte released as well as faster clearance when compared to control. The BM monocyte pool was similar in all groups. Monocyte transit time through BM: Exposure to EHC, CC only shortened the transit time of monocytes as compared to controls. AM + EHC also shortened monocyte transit time whereas AM + CC had a nonsignificant effect. |

| Reference: Gottipolu RR et al.(2009, 190360) Species: Rat Gender: Male Strain: Wistar Kyoto (WKY), SH Age: 14-16wks Weight: NR | DE (30-kW (40hp) 4-cylinder indirect injection Deutz diesel engine) (O ₂ - 20%, CO- 1.3-4.8ppm, NO- < 2.5- 5.9ppm, NO ₂ - < 0.25-1.2ppm, SO ₂ - 0.2-0.3ppm, OC/EC- 0.3±0.03) Particle Size: Number Median Diameter: Low- 83 ± 2nm, High- 88.2nm; Volume Median Diameter: Low- 207 ± 2nm, High- 225 ± 2nm | Route: Exposure Chamber Dose/Concentration: Low- 507 ± 4 µg/m ³ , High- 2201 ± 14 µg/m ³ Time to Analysis: Exposed 4h/d, 5d/wk, 4wks. Necropsied 1d postexposure. | DE increased neutrophils in a concentration-dependent manner, and GGT activity at the high dose. Particle-laden macrophages were found in DE-exposed rats. DE dose-dependently inhibited mitochondrial aconitase activity. DE caused 377 genes to be differentially expressed within WKY rats, most of which were downregulated, but none in SH rats. However, WKY rats had an expression pattern shift that mimicked baseline expression of SH rats without DE. These genes regulated compensatory response, matrix metabolism, mitochondrial function, and oxidative stress response. |
| Reference: Graff et al. (2005, 087956) Species: Rat Cell Type: Ventricular Myocytes | Zinc (Zn); Vanadium (V) Particle Size: NR | Route: Cell Culture Dose/Concentration: 0, 6.25, 12.5, 25, or 50 µM Time to Analysis: Toxicity: 24h post exposure Beat Rate: 0.5, 1, 2, 4, and 24h PE PCR: 6 and 24h PE | Beat Rate: There were statistically significant reductions in spontaneous beat rate 4 and 24 h post-exposure (greater reductions were observed with Zn). Inflammation: Exposure to Zn or V (6.25-50 µM) for 6h produced significant increases in IL-6, IL-α, heat shock protein 70, and connexin 43 (Cx43). Impulse Conduction: 24 h post-exposure, Zn induced significant changes in the gene expression of Kv4.2 and KvQLT, α-1 subunit of L-type Ca channel, Cx43, IL-6, and IL-1α. V produced a greater effect on Cx43 and affected only KvLQT1. |
| Reference: Gunnison and Chen (2005, 087956) Species: Mouse Gender: Male Strain: F2 generation DK (ApoE ^{-/-} , LDLr ^{-/-}) Age: 18-20wks | CAPs (Tuxedo, NY) Copolllutants measured: O ₃ and NO ₂ . Particle Size: 389 ± 2nm | Route: Whole-body Inhalation Dose/Concentration: CAPs: 131 ± 99 µg/m ³ (range 13 - 441 µg/m ³) O ₃ : 10 ppb NO ₂ : 4.4 ppb Time to Analysis: 6h/d, 5d/wk for approximately 4m. Tissue collection was performed 3-4d after the last day of exposure. | Gene expression: In CAPs-exposed heart tissue, the expression of Limd1 and Rex3 were the most consistently affected genes among the exposed mice. Limd1 was down regulated by 1.5-fold or greater from moderate baseline expression. Rex3 showed a relatively small increase in absolute expression. |
| Reference: Gurgueira et al. (2002, 036535) Species: Rat Gender: Male Strain: Sprague-Dawley Weight: 250-300g | CAPs; Carbon Black (CB from Fisher Scientific, Pittsburgh, PA): C (85.9 ± 0.2%); O (13 ± 0.2%); S (1.17 ± 0.02%) ROFA: obtained from an oil-fired power plant (Boston, MA) Particle Size: CAPs size range: 0.1- 2.5 µm; CB and ROFA (PM _{2.5}) | Route: Whole-body Exposure Chamber Dose/Concentration: CAPs: average mass concentration: 300 ± 60 µg/m ³ ; ROFA: 1.7 mg/m ³ ; CB: 170 µg/m ³ Time to Analysis: CAPs: 1, 3, and 5h; ROFA: 30min; CB: 5h | Oxidative stress: Rats breathing CAPs aerosols for 5 h showed significant oxidative stress, determined as in situ chemiluminescence (CL) in the lung, heart, but not in the liver. ROFA also triggered increases in oxidant levels but not particle-free air or CB. Increases in CL showed strong associations with the CAPs content of Fe, Al, Si and Ti in the heart. The oxidant stress imposed by 5h exposure to CAPs was associated with slight, but significant increases in the lung and heart water content, with increased serum levels of lactate dehydrogenase, indicating mild damage to tissues. CAPs inhalation also led to tissue-specific increases in the activities of SOD and catalase. |
| Reference: Gursinsky et al. (1976, 015607) Species: Rat Cell Type: Fibroblasts isolated from adult male Wistar rats hearts | Fly ash (TAF98) Particle Size: NR | Route: In Vitro Dose/Concentration: TAF98: 0, 1, 2 3, 10, 25, 50, 100, 200 µg/mL Time to Analysis: 0, 5, 10, 30, 60, 120min | Brief treatment of fibroblasts with fly ash triggered the immediate formation of ROS. Using phosphospecific antibodies the activation of p38 MAP kinase, p44/42 MAP kinase (ERK1/2) and p70S6 kinase. Prolonged incubation with fly ash increased the expression of collagen 1 and TGF-β1, but decreased mRNA levels of MMP9 and TNF-α. Cell proliferation was inhibited at high concentrations of fly ash. An increase in the level of advanced glycation end product modification of various cellular proteins was observed. |

Vasodilatation induced by sodium nitroprusside was not affected by any DEP exposure. |
| Reference: Harder et al. (2005, 087371) Species: Rat Gender: Male Strain: Wistar Kyoto Age: 12-15wks | Carbon UFPs (generated by Electric Spark Generator GFG 1000; Palas, Karlsruhe, Germany) Particle Size: 37.6 ± 0.7nm (mean) | Route: Whole-body Exposure Chamber Dose/Concentration: 180 µg/m ³ Time to Analysis: Days 1-3: baseline reading, Day 4: exposure to UFPs or filtered air for 4 or 24h then sacrificed immediately following exposure period OR Sacrificed following 1-3d recovery period. | Cardiovascular Performance: Mild but consistent increase in heart rate (HR), which was associated with a significant decrease in HR variability during exposure (particle-induced alteration of cardiac autonomic balance, mediated by a pulmonary receptor activation). Lung Inflammation and Acute-Phase Response: BALF revealed significant but low-grade pulmonary inflammation. Effects on Blood: There was no evidence of an inflammation-mediated increase in blood coagulability; no changes in plasma fibrinogen or factor VIIa. Pulmonary and Cardiac Histopathology: Sporadic accumulation of particle-laden macrophages found in the alveolar region. No signs of cardiac inflammation or cardiomyopathy. mRNA Expression Levels: No significant changes in the lung or heart. |
| Reference: Harder et al. (2005, 087371) Species: Rat Gender: Male Strain: Wistar Kyoto Age: 14-17wks Weight: NR | Carbon UFP Particle Size: Diameter: 37.6 ± 0.7nm | Route: Exposure Chamber Dose/Concentration: 180 µg/m ³ Time to Analysis: Telemeter implanted into peritoneal cavity. 10d recovery. 3d baseline reading. 24h exposure. 3d recovery. | Carbon UFP mildly but significantly elevated HR compared to the control. SDNN was significantly decreased during exposure. UFP induced mild pulmonary inflammation, significantly increased PMN, and increased the total protein and albumin concentrations. Particle-laden macrophages sporadically accumulated in the alveolar region. |
| Reference: Hirano et al. (2003, 097345) Species: Rat Cell Types: Heart Microvessel Endothelial Cells (RHMEV) | Organic Extracts of DEP (DEP) and Organic Extracts of Ultra Fine Particles (UFP). (Urawa City, Saitama, Japan) Particle Size: DEP and UFP: < 2.0 µm | Route: Cells Culture Dose/Concentration: NAC effects on viability: DEP: 25 µg/ml; UFP: 50 µg/ml mRNA levels for DEP and UFP: 0, 1, 3, 10 µg/ml cell monolayer exposed to DEP and UFP: 1, 10, 100 µg/ml Time to Analysis: mRNA levels measured after 6h incubation with DEP or UFP. Other parameters measured after 24h. | Cytotoxicity and Oxidative Stress: LC50 values were 17 and 34 µg/mL for DEP and UFP respectively. The viability of DEP and UFP exposed cells was ameliorated by N-acetyl-L-cysteine (NAC). mRNA levels: mRNA levels increased dose-dependently with DEP and HO-1 mRNA showed the most marked response to DEP. mRNA levels of antioxidant enzymes and heat shock protein 72 (HSP72) in DEP-exposed cells were higher than UFP exposed cells at the same concentration. The transcription levels of HO-1 and HSP72 in DEP and UFP-exposed cells were also reduced by NAC. |

| Reference: Hwang et al. (2005, 089454) Species: Mouse Strain: Normal (C57) and ApoE ^{-/-} | CAPs (Tuxedo, NY) Particle Size: 389 ± 2nm | Route: Whole-body Inhalation Dose/Concentration: CAPs Range: 5-627 µg/m ³ . Mean CAPs Concentration: 133µg/m ³ . Mean Concentrations of Ozone and Nitrogen in CAPs: 10 and 4.4 ppb respectively. Time to Analysis: 6h/day, 5d/wk for 5m. | Long-term Analysis: Significant decreasing patterns of heart rate (HR), body temperature (T), and physical activity (PA) in ApoE ^{-/-} mice. Nonsignificant changes for C57 mice. The chronic effect changes for HR, T, and PA for ApoE ^{-/-} mice were maximal in the last three weeks. Short-term Analysis: Dose-dependent relationship for HR variations in ApoE ^{-/-} mice. Heart Rate Fluctuation: HR fluctuations in Apo E ^{-/-} mice during the period of 3-6 h increased by 1.35 fold at the end of the exposure and during a 15 min period increases by 0.7 fold at the end of the exposure. |
| Reference: Inoue et al. (2006, 190142) Species: Mouse Gender: Male Strain: ICR Age: 6-7wks | DEP (obtained from a 4Jb1-type light-duty, 4-cylinder, 2.74-L Isuzu diesel engine) Washed DEP (carbonaceous nuclei of DEP after extraction) and DEP-OC (organic chemicals in DEP extracted with CH ₂ Cl ₂); Washed DEP + LPS and DEP-OC + LPS Particle Size: PM _{2.5} | Route: IT Instillation Dose/Concentration: Washed DEP: 4mg/kg bw. DEP-OC: 4mg/kg bw. LPS: 2.5mg/kg. Washed DEP + LPS and DEP-OC + LPS: respective additions of LPS to each component prior-experimentation. Time to Analysis: Sacrificed 24h post single dose instillation. | Both DEP components exacerbated vascular permeability. The increased fibrinogen and E-selectin levels induced by LPS. This exacerbation was more prominent with washed DEP than with DEP-OC. Washed DEP + LPS significantly decreased protein C and antithrombin-III and elevated circulatory levels of IL-6, KC and LPs without significance. |
| Reference: Ito et al. (2008, 096823) Species: Rat Gender: Male Strain: Wistar Kyoto (Specific pathogen-free) Age: 13-14 wks | CAPs (f-PM) from Inhalation Facility in Yokohama City, Japan. Particle Size: 0.1-2.5 µm | Route: Whole-body Inhalation Dose/Concentration: 0.6-1.5 mg/m ³ Time to Analysis: Three groups exposed to: (1) filtered air for 4d, (2) filtered air for 3d and CAPs for 1d or (3) CAPs for 4d. All groups exposed for a maximum of 4.5h/d for 4 consecutive days. | mRNA expression and cardiovascular function: In samples of heart tissue, the mRNA of cytochrome P450 (CYP) 1B1, heme oxygenase-1 (HO-1), and endothelin A (ETA) receptor were up-regulated by CAPs; their levels were significantly correlated with the cumulative weight of CAPs in the exposure chamber. The up-regulation of ETA receptor mRNA was significantly correlated with the increase in HO-1 mRNA and weakly with the increase in MBP. |
| Reference: Khandoga A et al. (2004, 087928) Species: Mouse Gender: Female Strain: C57B1/6 Age: 5-7wks | UFPs: Ultra fine carbon black particles (Printex 90) Particle Size: 14nm diameter (60 % < 100nm) | Route: Aortic Infusion Dose/Concentration: 1 x 10 ⁷ and 5 x 10 ⁷ total particles infused 300 m ² /g surface area Time to Analysis: Single exposure, analysis 2h post exposure | Platelet effects: Application of UFPs caused significantly enhanced platelet accumulation on endothelium of postsinusoidal venules and sinusoids in healthy mice. UFP-induced platelet adhesion was not preceded by platelet rolling but was strongly associated with fibrin deposition and an increase in vWF expression on the endothelial surface. Inflammatory effects: In contrast, inflammatory parameters such as the number of rolling/adherent leukocytes, P-selectin expression/translocation, and the number of apoptotic cells were not elevated. UFPs did not affect sinusoidal perfusion and Kupffer cell function. |
| Reference: Knuckles et al. (2007, 156652) Species: Rat Gender: Female (Pregnant, purchased at gestation day 19) Strain: Sprague-Dawley Age: 60-90d Weight: 300g Use: RMCs were harvest from 1d-old neonatal pups using the neonatal rat cardiomyocyte isolation kit | ROFA-L: Leachate Particle Size: < 0.2 µm | Route: Cell Culture Dose/Concentration: 3.5 µg/mL Time to Analysis: 1h | ROFA-L induced alterations to the RCM transcriptome: 38 genes were suppressed and 44 genes were induced PE. Genomic alterations in pathways related to IGF-1, VEGF, IL-2, PI3/AKT, CVD, and free radical scavenging were detected. Global gene expression was altered in a manner consistent with cardiac myocyte electrophysiological remodeling, cellular oxidative stress and apoptosis. ROFA-L induced alterations to the RCM transcription factor proteome: ROFA-L altered the transcription factor proteome by suppressing activity of 24 and activating 40 transcription factors out of 149. |

| Reference: Knuckles et al. (2008, 191987) Species: Mouse Gender: Male Strain: C57BL/6 Age: 8-10wks Weight: NR | DE (single cylinder Yanmar diesel generator burning #2 certified diesel fuel (Chevron-Phillips, Borger, TX) under 100% load) Particle Size: PM _{2.5} | Route: Whole-body Exposure. Ex Vivo. Dose/Concentration: In vivo: 350 µg/m ³ ; Ex vivo: PM _{2.5} concentration 2.3mg/m ³ flow rate 500mL/min Time to Analysis: Exposed 4h. Ex vivo assays. | Veins: DE increased vascular reactivity to ET-1. Ex vivo exposed vessels had greater vasoconstriction. L-NAME (an arginine blocker) did not promote constriction in DE-exposed rats but did so in controls. Arteries: DE did not significantly alter vascular reactivity. Carbonyls or alkanes alone or with DE did not alter vasoconstriction. |
| Reference: Kodavanti et al. (2008, 155907) Species: Rat Gender: Male Strain: Wistar Kyoto (WKY) Age: 12-14wks | G1: saline (control); G2: Mount Saint Helen's ash (SH); G3: whole suspension of oil combustion PM at high concentration (PM-HD); G4: whole suspension of oil combustion PM at low concentration (PM-LD); G5: saline-leachable fraction of PM high-concentration suspension; G6: ZnS 7H2O Particle Size: PM _{2.5} | Route: IT Instillation Dose/Concentration: Doses (mg/kg/week) are for 8 and 16 weeks (PM-solid and soluble Zn) respectively. G1: 0.00-0.00 and 0.00-0.00; G2: 4.60-0.00 and 2.30-0.00; G3: 4.60-66.8 and 2.30-33.4; G4: 2.30-33.4 and 1.15-16.7; G5: 0.00-66.8 and 0.00-33.4; G6: 0.00-66.8 and 0.00-33.4 Time to Analysis: 1x/wk for 8 or 16wks; analyzed 48h after last instillation. | DNA damage (left ventricular tissue): All groups except MSH caused varying degrees of damage relative to control. Total cardiac aconitase activity was inhibited in rats receiving soluble Zn. Analysis of heart tissue revealed modest changes in mRNA for genes involved in signaling, ion channels function, oxidative stress, mitochondrial fatty acid metabolism, and cell cycle regulation in Zn, but not MSH-exposed rats. |
| Reference: Kyoso M et al. (2005, 186998) Species: Rat Gender: NR Strain: NR Age: 15m | DE PM and NO _x exposures Particle Size: NR | Route: Whole-body Inhalation Dose/Concentration: PM (mg/m ³): 0.01, 0.109, 0.54, 1.09, 0.01 (from 1.09 concentration w/o PM) NO _x (ppm): 0.19, 0.59, 2.60, 5.53, 5.47 (w/o PM) Time to Analysis: Exposed 16h/d (from 5pm-9am) for 7m | All of the resting R-R intervals before exposure were lower at night than during the day, but few changes were found after exposure. |
| Reference: Lei YC et al. (2005, 088660) Species: Rat Gender: Male Strain: Sprague-Dawley Weight: 200-250g (upon arrival) Use: ip STZ (60 mg/kg bw) dissolved in citric acid buffer administered to 8 rats to induce diabetes; ip citric acid buffer administered to 8 non-diabetic rats | CAPs: Hsin-Chuang, Taipei Particle Size: PM: 0.01 - 2.5 µm | Route: IT Instillation Dose/Concentration: PM _{2.5} : 200 µg in 0.5 mL saline. Components (µg/m ³): Organic Carbon (9.8-SD 2.4)), Elemental Carbon (3.6-SD 3.2), Sulfate (4.8-SD 1.2), Nitrate (6.3-SD 3.4) Time to Analysis: Single dose. Animals sacrificed 24h post instillation. | Effects of Diabetes: Body weight (bw) of diabetic (D) rats (397.5g) was lower than non-diabetic (ND) rats (483.1g). Mean plasma glucose level was 163 mg/dL in ND rats and 448.2 mg/dL in D rats. D rats had significant greater levels of 8-OHdG in plasma compared to ND rats. D rats had significantly increased levels of plasma [nitrate + nitrite]. No observable changes in TNF-α for D and ND rats. Effects of PM Exposure ND Rats: Increase in plasma levels of 8-OHdG and plasma IL-6, TNF-α, and serum CRP. Significant reduction of plasma [nitrate + nitrite]. No significant effect on plasma ET-1. Effects of PM Exposure STZ-D Rats: Significant elevation of plasma ET-1. Decrease in plasma [nitrate + nitrite] Plasma 8-OHdG and TNF-α significantly increased. No significant alterations in IL-6 and CRP. |
| Reference: Lemos M et al. (2006, 088594) Species: Mouse Gender: NR Strain: BALB/c Age: 1d (neonatal) n: 10 Weight: 4-6g | PM ₁₀ , CO, NO ₂ , and SO ₂ from Universidade de Sao Paulo, Brazil. Particle Size: PM ₁₀ | Route: Inhalation via Whole-body exposure Dose/Concentration: Mean (± SD) concentrations were: CO ₂ : 2.06 ± 0.08ppm (8h mean); NO ₂ : 104.75 ± 42.62 µg/m ³ (24h mean); SO ₂ : 11.07 ± 5.32 µg/m ³ (24h mean); PM ₁₀ : 35.52 ± 12.84 µg/m ³ (24h mean) Time to Analysis: 24 h/d, 7d/wk for 4m | Morphometric measurements of the ratio between the lumen and the wall (L/W) areas were performed on transverse sections of renal, pulmonary and coronary arteries. A significant decrease of L/W with exposure to air pollution was detected in pulmonary and coronary arteries, whereas no effects of air pollution were observed in renal vessels. |

| Reference: Li et al. (2005, 088647) Species: Human and Rat Strain: Sprague-Dawley Rats Tissues/Cell Types: Cultured HPAECs; Pulmonary Artery Rings (PARs) | Urban Particles (UPs SRM 1648) Major Constituents (mass fraction in %): Al (3.4), Fe (3.9), K (1.1). Minor Constituents (mass fraction in %): Na (0.43), Pb (0.66), Zn (0.48). Trace Constituents (ng/mg): As (115), Cd (75), Cr (403), Cu (609), Mn (786), Ni (82), Se (27), U (5.5), V (127). Particle Size: NR | Route: PARs: In vitro organ model HPAECs: grown to 80% confluence Dose/Concentration: PARs and HPAECs: 1 to 100 μ g/mL; Losartan treatment: 0.2 μ mol Captopril treatment: 100 μ mol Time to Analysis: PARs were exposed to increasing doses of UPs from 1 to 100 μ g/mL. Maximum tension was recorded within 5min after each UPs dose. HPAECs: exposed to UPs from 1 to 100 μ g/mL for up to 20min | Effects of UPs on the constriction of isolated rat pulmonary PARs and the activation of extracellular signal-regulated kinases 1 and 2 (ERK1/2) and p38 mitogen-activated protein kinases (MAPKs) in HPAECs with or without Losartan at 1-100 μ g/mL induced acute vasoconstriction. UPs also produced a time- and dose-dependent increase in phosphorylation of ERK1/2 and p38 MAPK. Losartan pre-treatment inhibited both vasoconstriction and activation of ERK1/2 and p38. The water soluble fraction of UPs was sufficient for inducing ERK1/2 and p38 phosphorylation, which was also inhibited by Losartan. Cu (CuSO ₄) and V (VOSO ₄), induced pulmonary vasoconstriction and phosphorylation of ERK1/2 and p38, but only phosphorylation of p38 was inhibited by Losartan. UPs induced activation of ERK1/2 and p38 was attenuated by Captopril. |
| Reference: Li et al. (2006, 156693) Species: Rat, Rabbit, and Human Tissues/Cell Types: Pulmonary Artery Rings (PARs) (rat); isolated buffer-infused lungs (rabbits) and cultured HPAECs Strain: Sprague Dawley Rats, New Zealand White Rabbits Weight: Rat: 200-350g; Rabbit: 2.5-3.0kg | Urban Particles (UPs SRM 1648). Major Constituents (mass fraction in %): Al (3.4), Fe (3.9), K (1.1). Minor Constituents (mass fraction in %): Na (0.43), Pb (0.66), Zn (0.48). Trace Constituents (ng/mg): As (115), Cd (76), Cr (403), Cu (609), Mg (786), Ni (82), Se (27), U (5.5), V (127). Particle Size: NR | Route: In Vitro Dose/Concentration: PARs and HPAECs: 1 to 100 μ g/mL; Time to Analysis: PARs: treatment given 15min prior to exposure. Exposed to increasing doses of UPs from 1 to 100 μ g/mL. Maximum tension was recorded within 5min after each UPs dose. HPAECs: exposed to UPs from 1 to 100 μ g/mL for 20 and 120min. | Effects of UP on H₂O₂ release: Within minutes after UPs treatment, HPAEC increased H ₂ O ₂ production that could be inhibited by DPI, APO, and NaN ₃ . The water soluble fraction of UPs as well as its two transition metal components Cu and V, also stimulated H ₂ O ₂ production. NaN ₃ inhibited H ₂ O ₂ production stimulated by Cu and V, whereas DPI and APO inhibited only Cu-stimulated H ₂ O ₂ production. Inhibitors of other H ₂ O ₂ -producing enzymes, including N-methyl-L-arginine, indomethacin, allopurinol, cimetidine, rotenone, and antimycin, had no effects. Effects of UP-induced H₂O₂ on MAPK activation: DPI but not NaN ₃ attenuated UPs-induced pulmonary vasoconstriction and phosphorylation of ERK1/2 and p38 MAPKs. Knockdown of p47phox gene expression by small interfering RNA attenuated UPs-induced H ₂ O ₂ production and phosphorylation of ERK1/2 and p38 MAPKs. |
| Reference: Lippmann et al. (2005, 087453) Species: Mouse Strain: C57 and ApoE ^{-/-} | (March-September 2003). Chemical Composition: regional secondary sulfate (SS) characterized by high S, Si, and organic C; resuspended soil (RS) characterized by high concentrations of Ca, Fe, Al, and Si; RO-fired powered emissions of the Eastern U.S. identified by the presence of V, Ni, and Se; and motor vehicle (MV) traffic and other sources. Contributors to Average Mass: SS (56.1%), RS (11.7%), RO combustion (1.4%), MV traffic and other sources (30.9%) Particle Size: PM _{2.5} | Route: Whole-body Inhalation Dose/Concentration: PM _{2.5} concentrated ten-fold, producing an average of 113 μ g/m ³ Time to Analysis: 6h/d, 5d/wk for 5m. Parameters measured daily: during exposure, the afternoon after exposure, and late at night | Associations between sources and short-term Heart Rate changes: There were no significant associations between SS, RS, RO, and MV factors and HR in C57 mice at any of the three intervals. There were significant associations between PM _{2.5} and the RS source factor and decreases in HR for the ApoE ^{-/-} mice during the daily CAPs exposures but no associations with the other factors. There was no residual association of HR with PM _{2.5} or the RS factor later in the afternoon or late at night. In the afternoon, there was a significant association between decreases in HR and the SS factor for the ApoE ^{-/-} mice that had not been present during exposure and did not persist into the night time period. MV traffic and others were not significantly associated with HR during any of these three time periods. For the C57 mice, there were no significant associations of HR with PM _{2.5} or any of its components during any of the three daily time periods. Associations between sources and short-term HRV changes: Signal noise during exposures did not permit reliable analyses of HRV changes during the hours of CAP exposure. |

| Reference: Lippmann et al. (2005, 087453) Species: Mouse Gender: NR Strain: ApoE ^{-/-} , ApoE ^{-/-} LDLr ^{-/-} , C57BL/6 Age: NR Weight: NR | CAPs (Sterling Forest, spring-summer 2003) Particle Size: PM _{2.5} | Route: Inhalation Dose/Concentration: PM _{2.5} average concentration: 110 µg/m ³ , Long-term average: 19.7 µg/m ³ Time to Analysis: Exposed 6h/d, 5d/wk, 5 or 6m. Semicontinuous EKG recordings. | HR increased in ApoE ^{-/-} mice but not C57 mice. HRF increased over the duration of the experiment. Atherosclerotic plaque deposits and coronary artery disease lesions occurred in both CAPs-exposed mice and controls, but invasive lesions were only present in CAPs-exposed mice. A gene affecting circadian rhythm was upregulated in double knockout mice. CAPs activated NF-κB. No inflammation occurred in the pulmonary system. |
| Reference: Lippman M et al. (2006, 091165) Species: Mouse Gender: Male Strain: ApoE ^{-/-} Age: 6wks | CAPs from Tuxedo, NY. Component of interest: Ni. Particle Size: PM _{2.5} | Route: Whole-body Inhalation Dose/Concentration: Average daily CAPs: 85.6 µg/m ³ Average daily Ni: 43 ng/m ³ Time to Analysis: 6h/d, 5d/wk, for 6m (July 2004-January 2005). 10-second ECG, HR, activity, and body temperature data were sampled every 5min for the duration of the experiment. | For the CAPs-exposed mice, on 14 days there were Ni peaks at approximately 175 ng/m ³ and usually low CAPs and V. For those days back-trajectory analysis identified a remote Ni point source. ECG measurements on CAPs-exposed and sham-exposed mice showed Ni to be significantly associated with acute changes in HR and HRV. |
| Reference: Lund et al. (2007, 125741) Species: Mouse Gender: Male Strain: ApoE ^{-/-} Age: 10wks Use: Mice were placed on a high fat at the beginning of the exposure. | Varying dilutions of gasoline emissions: (generated using two 1996 model 4.3L General Motors V-6 engines, fueled with conventional, unleaded, non-oxygenated gasoline, equipped with stock exhaust systems). Composition for Hi, Med, and Lo dilutions: PM, NO _x , CO, and Total Hydrocarbons (THC) Particle Size: NR | Route: Whole-body Inhalation Dose/Concentration: FA: PM (2 µg/m ³), NO _x (0 ppm), CO (0.1 ppm), HC (0.1 ppm); Low (1: 90 dilution of exhaust): PM (8 µg/m ³), NO _x (2 ppm), CO (9 ppm), HC (0.9 ppm); Mid (1: 20): PM (39 µg/m ³), NO _x (12 ppm), CO (50 ppm), HC (8.4 ppm); High (1: 12): PM (61 µg/m ³), NO _x (19 ppm), CO (80 ppm), HC (12 ppm); High-filtered (1:12): PM (2 µg/m ³), NO _x (18 ppm), CO (80 ppm), HC (12.7 ppm). Time to Analysis: 6h/d, 7d/wk for 7wks. Mice were sacrificed within 16h PE. During the study period all animals concurrently exposed to the following: FA: 8 µg/m ³ and 40 µg/m ³ ; PM Whole Exhaust: 60 µg/m ³ ; or Filtered Exhaust w/ gases matching the 60 µg/m ³ concentration. | Inhalation exposure to gasoline engine emissions resulted in increased aortic mRNA expression of matrix metalloproteinase-3 (MMP-3), MMP-7, and MMP-9, tissue inhibitor of MMP-2, ET-1 and HO-1 in ApoE ^{-/-} mice; increased aortic MMP-9 protein levels were confirmed through immunohistochemistry. Elevated ROS were also observed in arteries from exposed animals, despite absence of plasma markers. Similar findings were also observed in the aortas ApoE ^{-/-} mice exposed to particle filtered atmosphere, implicating the gaseous components of the whole exhaust in mediating the expression of markers associated with vasculopathy. |
| Reference: Lund AK et al. (2009, 191159) Species: Mouse Gender: Male Strain: ApoE ^{-/-} Age: 10wks Weight: NR | GEE (conventional unleaded, nonoxygenated, nonreformulated gasoline- ChevronPhillips Specialty Fuels Division) Particle Size: PM: MMAD- 0.150 µm | Route: Inhalation Dose/Concentration: PM: 60 µg/m ³ , NO ₂ : 2ppm, NO: 16ppm, CO: 80ppm, THC: 12.7ppm Time to Analysis: Mice fed high-fat diet 30d before exposure. Exposed 6h/d, 1 or 7d. Some groups dosed with Tempol or BQ-123. Killed within 18h of last exposure. | Aorta gelatinase activity increased with GEE exposure time. MMP-2/9 activity spread throughout the vasculature by day 7. 7d GEE exposure significantly increased the aorta protein expression of MMP-9, MMP-2, TIMP-2, and plasma MMP-9. Generally, in GEE-exposed mice, Tempol decreased TBARS and vascular ET-1, and BQ-123 decreased vascular ROS, ET-1, MMP-9, and gelatinase activity. |
| Reference: Lund AK et al. | Reference: Nemmar A et al. (2007, 156800) Species: Rat Gender: Male Strain: Wistar Kyoto Age: 16wks Weight: 424 ± 8g | DEP (SRM 2975) Particle Size: NR | Route: Tail Vein Injection Dose/Concentration: 8, 42, or 212 µg DEP/rat (150ul of 0.02, 0.1, or 0.5 mg/kg bw) Time to Analysis: 24h | Effect of DEP on Blood Pressure: Significant decrease on BP in DEP-exposed rats at doses of 0.02 mg/kg bw, compared with mean BP observed in controls. Effect of DEP on HR: Doses of 0.02, 0.1, and 0.5 mg/kg bw in rats, resulted in significant reduction of HR compared to controls. Effect of DEP on Tail Bleeding Time: Shortening of tail bleeding time in rats exposed to 0.02, 0.1, and 0.5 mg/kg bw. The shortening was significant at the dose of 0.02 and 0.5 mg/kg compared w/ controls. Platelet counts in blood did not significantly increased post-DEP administration. Effect of DEP on WBC and RBC numbers: No significant effect of DEP at doses of 0.02, 0.1 and 0.5 mg/kg on the numbers of granulocytes, monocytes, or lymphocytes compared with control. |
| Reference: Nemmar et al. (2003, 096567) Species: Hamster Gender: Male and Female Weight: 100-110g | DEP (SRM 1650) Particle Size: NR | Route: IT Instillation Dose/Concentration: 120 µl (5, 50, or 500 µg/animal) Time to Analysis: In-vivo: formation and embolization of thrombus were continuously monitored for 40min. Ex-vivo: animals were ITly instilled w/ DEPs (0 or 50 µg per animal), and blood was collected 5, 15, 30, and 60min post-instillation. In-vitro: Saline or saline-containing DEPs (0.1, 0.5, 1, and 5 µg/mL) was added to venous blood from untreated hamsters, and closure time was measured in the PFA-100 after 5min/animal. | Doses of 5 – 500 µg enhanced experimental arterial and venous platelet-rich thrombus formation in-vivo. Blood samples taken from hamsters 30 and 60 min after instillation of 50 µg of DEPs yielded accelerated aperture closure (platelet activation) ex-vivo, when analyzed in the PFA-100. The direct addition of as little as 0.5 µg/mL DEPs to untreated hamster blood significantly shortened closure time in vitro. |
| Reference: Nemmar et al. (2004, 087959) Species: Hamster Gender: Male and Female Weight: 100-110g | DEP (SRM 1650); Positively Charged Polystyrene Particles (PCPSP) Particle Size: PCPSP: 400 nm; DEP: NR | Route: IT Instillation Dose/Concentration: DEP: 50 µg/animal, or PCPSP: 500 µg/animal Time to Analysis: Pretreatment Phase: Hamsters were pretreated w/ Dexametasone IP (5mg/kg) or IT (0.1 or 0.5mg/kg) or Sodium Cromoglycate given IP (40mg/kg), 1h before DEP or vehicle instillation. Thrombosis: In-vivo thrombogenesis assessed 24h post-instillation of DEP or vehicle. | DEP increased thrombosis without elevating plasma vWF. The IT instillation of PCPSP equally produced histamine release and enhanced thrombosis. Histamine in plasma resulted from basophil activation. IP pretreatment with Dexametasone abolished the DEP-induced histamine increase in BALF and plasma and abrogated airway inflammation and thrombogenicity. The IT pretreatment with Dexametasone showed a partial but parallel inhibition of all these parameters. Pretreatment with Sodium Cromoglycate strongly inhibited thrombogenicity, and histamine release. |
| Reference: Nemmar et al. (2003, 087487) Species: Hamster Gender: Male and Female Weight: 100-110g | Ultrafine Particles: Unmodified Polystyrene Particles (UPSPs); Negatively Charged Carboxylate-Modified Polystyrene Particles (NCC-MPSPs); Positively-Charged Amine Modified Polystyrene Particles (PCA-MPSPs) Particle Size: UPSPs: 60nm; NCC-MPSPs: 60nm; PCA-MPSPs: 60 or 400nm | Route: IT Instillation Dose/Concentration: 5, 50, and 500 µg/animal in 120 ul saline Time to Analysis: 1h post-instillation | Unmodified and negative UFPs did not modify thrombosis. Positive UFPs increased thrombosis at 500 and 50 µg/animal, but not at 5 µg/animal. Positive 400 nm particles (500 µg/animal) did not affect thrombosis. PFA-100 analysis showed that platelets were activated by the in-vitro addition of positive UFPs and 400 nm particles to blood. |
| Reference: Nemmar et al. (2003, 087931) Species: Hamster Weight: 100-110g | DEP (SRM 1650) Particle Size: NR | Route: IT Instillation Dose/Concentration: 50 µg/animal in 120 ul saline Time to Analysis: 1, 3, 6, and 24h | At 1, 6, and 24 h after instillation of 50 µg DEPs, the mean size of in-vivo induced and quantified venous thrombosis was increased by 480, 770, and 460%, respectively. Platelets activation in blood was confirmed by a shortened closure time in the PFA-100 analyzer. In plasma, histamine was increased only at 6 and 24 h. Pre-treatment with a H1 receptor antagonist (diphenhydramine, 30 mg/kg intraperitoneally) did not affect DEP-induced thrombosis or platelet activation at 1 h; however both were markedly reduced at 6 and 24 h. |

| Reference: Niwa et al. (2007, 091309) Species: Mouse Gender: Male Strain: LDLR/KO Age, Use: 6 weeks (n = 20), IT CB dispersion; 10-14wks acute effect of CB dispersion on circulating CRP | Carbon Black Particle Size: 23-470nm (mean size 120.7nm) | Route: IT Dispersion Dose/Concentration: IT CB Dispersion Study: 1 mg per animal/week; Acute Effect of CB Dispersion on Circulating CRP Study: 1mg/animal (single administration) Time to Analysis: IT CB Dispersion Study: 1x/wk for 10wks; Acute Effect of CB Dispersion on Circulating CRP Study: Single CB administration, blood samples collected 24h post-administration | IT CB Dispersion Study: Although no difference in body weight (bw) between the four groups was observed at baseline, and all mice experienced an increase in bw with advancing age, the mice treated with CB tended to be smaller than those treated with vehicle (air). No significant differences were observed in cholesterol and TG levels among the four groups. Development of aortic lipid-rich lesions occurred in mice under a 0.51% cholesterol diet with or without CB infusion, but not in the mice fed a 0% cholesterol diet. Acute Effect of CB Dispersion on Circulating CRP Study: Circulating levels of CRP were significantly higher in mice exposed to CB versus those exposed to air, indicating an acute inflammatory response. Although the presence of CB in pulmonary macrophage-like cells in CB treated mice under 0.51% cholesterol diet was confirmed, CB was not detected in aortas, livers, kidneys, or spleens. |
| Reference: Niwa et al. (2007, 091309) Species: Mouse Cell Types: Macrophages Cell Lines (RAW264.7) | Carbon Black (CB); Water-Soluble Fullerene (C60(OH)24); Fluoresbrite Carboxylate Microspheres; Ox-LDL; Acetylated-LDL Particle Size: Carbon Black and C60(OH)24: 7.1nm (SD 2.4); Fluoresbrite Carboxylate Microspheres: 6nm | Route: Cell Culture Dose/Concentration: CB: 1, 10, 100 µg/mL; C60(OH)24: 20, 100ng/mL Time to Analysis: RAW264.7 + CB for 24h, 13d, and 50d; RAW264.7 + C60(OH)24 for 24h or 10d; RAW264.7 + C60(OH)24 for 8d, then co-treated w/ Ox-LDL for an additional 48h; RAW264.7 + Ox-LDL for 5d, and then co-cultured w/ C60(OH)24 for an additional 48h; RAW264.7 + 6nm beads: 3d, the Ox-LDL or acetylated-LDL added for 24h | CB alone had no significant effects on RAW264.7 cell growth. C60(OH)24 alone or CB and C60(OH)24 together w/ Ox-LDL induced cytotoxic morphological changes, such as Ox-LDL uptake-induced foam cell-like formation and decreased cell growth, in a dose-dependent manner. C60(OH)24 induced LOX-1 protein expression, pro-matrix metalloproteinase-9 protein secretion, and tissue factor mRNA expression in lipid-laden macrophages. Although CB or C60(OH)24 alone did not induce platelet aggregation, C60(OH)24 facilitated ADP-induced platelet aggregation. C60(OH)24 also acted as a competitive inhibitor of ADP receptor antagonists in ADP-mediated platelet aggregation. |
| Reference: Niwa Y et al. (2008, 156812) Species: Rat Strain: Sprague-Dawley Age: 6wks | CB from Kyoto, Japan Particle Size: Mean size (nm) ± SD determined at 1, 8, 15, 22, and 29d post-exposure was 118.1 ± 2.4, 119.1 ± 2.7, 122.2 ± 2.0, 122.4 ± 2.5 and 121.0 ± 3.6 respectively | Route: Whole-body Inhalation Dose/Concentration: 15.6 ± 3.5mg/m ³ Time to Analysis: 6h/d, 5d/wk, for a total of 4wks. BP and HR were measured by tail-cuff plethysmography at 1, 14, and 28d post-exposure. Sacrificed At 1, 7, 14, 28, and 30d post-exposure | Although the presence of CB was confirmed in pulmonary macrophages, electron microscopic survey did not detect CB in other tissues including, liver, spleen and aorta. CB exposure raised blood pressure levels in a exposure-time dependent manner. Levels of circulating inflammatory marker proteins, including monocyte chemo attractant protein-1, IL-6, and CRP, were higher in the CB treated groups than in control groups. |
| Reference: Nurkiewicz TR et al. (2004, 087968) Species: Rat Gender: Male Strain: Sprague-Dawley Age: 7-8wks | ROFA (from Everett, MA) Major metal contaminants are: Fe, Al, V, Ni, Ca, and Z. Main soluble metals are: Al, Ni, and Ca. Particle Size: ROFA mean count diameter: 2.2 µm | Route: IT Instillation Dose/Concentration: ROFA group: 0.1, 0.25, 1, or 2mg/rat. Vehicle control group: 300 ul saline. Particle control group: TiO ₂ 0.25mg/rat. Time to Analysis: After single IT instillation of a particular dose, all rats recovered for 24h. | Saline Treated Rats: A23187 dilated arterioles up to 72 ± 7% max. ROFA and TiO₂ Exposed Rats: A23187-induced dilation was significantly attenuated. Sensitivity of Arteriolar Smooth Muscle to NO: Similar in saline treated and ROFA exposed rats. Other: Significant increase in venular leukocyte-adhesion and rolling observed in ROFA exposed rats. |

| Study | Pollutant | Exposure | Effects |
|---|--|--|--|
| Reference: Nurkiewicz et al. (2006, 088611) Species: Rat Gender: Male Strain: Sprague-Dawley Age: 7-8wks | ROFA from Everett, MA Particle Size: ROFA mean count diameter: 2.2 μm ; TiO ₂ mean diameter: 1.0 μm | Route: IT Instillation Dose/Concentration: ROFA group: 0.1 or 0.25 mg/rat. Vehicle control group: 300 μl saline. Particle control group: TiO ₂ 0.1 or 0.25 mg/rat. Time to Analysis: After single IT instillation of a particular dose, all rats recovered for 24h. | ROFA or TiO₂ Exposure and Arteriolar Dilation: Exposure caused a dose-dependent impairment of endothelium-dependent arteriolar dilation. ROFA or TiO₂ Exposure and Arteriolar Constriction: Exposure did not affect microvascular constriction in response to PHE. ROFA and TiO₂ and Leukocyte Rolling and Adhesion: Exposure significantly increased leukocyte rolling and adhesion in aird venules, and these cells were identified as PMN leukocytes. ROFA and TiO₂ and MPO: MPO was found in PMN leukocytes, adhering to the systemic microvascular wall. Evidence suggests that some of this MPO had been deposited in the microvascular wall. There was also evidence of oxidative stress in the microvascular wall. |
| Reference: Nurkiewicz TR et al. (2008, 156816) Species: Rat Gender: Male Strain: SD Age: 6-7wks Weight: NR | TiO ₂ (DeGussa, Sigma-Aldrich; powders put through fluidized-bed aerosol generator) Particle Size: Fine- 1 μm , UF- 21nm | Route: Whole-body Exposure Dose/Concentration: Concentrations: Fine- 3-16mg/m ³ ; UF- 1.5-12mg/m ³ ; Dose: Fine- 8, 20, 36, 67, 90 μg ; UF- 4, 6, 10, 19, 30 μg Time to Analysis: Acclimated 5d. Exposed 4-12h. Sacrificed 24h postexposure. | Particle accumulation within AMs, anuclear macrophages, particle-laden AMs intimately associated with the alveolar wall were all present in exposed rats. Calcium ionophore impaired arteriolar dilation in a dose-dependent manner in UF and fine exposed rats. UF produced greater systemic microvascular dysfunction. Microvascular dysfunction was the same for three groups of rats exposed to 30 μg UF TiO ₂ under different conditions. |
| Reference: Nurkiewicz et al. (2009, 191961) Species: Rat Gender: Male Strain: SD Age: 7-8wks Weight: NR | Fine TiO ₂ (Sigma-Aldrich- (titanium (IV)) oxide, 224227, St. Louis, MO) (~ 99% rutile) TiO ₂ nanoparticles (DeGussa-Aeroxide TiO ₂ P25, Parsippany, NJ) (80% anatase, 20% rutile) Particle Size: Fine TiO ₂ - Primary size: < 5 μm , MMAD: 402nm, CMD: 710nm; Nano-TiO ₂ - Primary size: 21nm, MMAD: 138nm, CMD: 100nm | Route: Aerosol Inhalation Dose/Concentration: 1.5-16mg/m ³ Time to Analysis: Acclimated 5d. Exposed 240-720min. Anesthetized 24h postexposure. Intravital microscopy, NO measurement, microvascular oxidative stress measurement, nitrotyrosine staining. | Arteriolar Dilation: Nano-TiO ₂ significantly impaired endothelium-dependent arteriolar dilation. Equivalent levels of arteriolar dysfunction were found in fine and nano-TiO ₂ . Arteriolar dilation in response to abluminal microiontophoretic application of SNP was not different from the controls or between the exposure groups. Arteriolar dilation was partially restored by radical scavenging with TEMPOL and catalase, NADPH oxidase with apocynin, and MPO inhibition with ABAH. Microcirculation: ROS increased in both groups. Nano-TiO ₂ significantly increased the area of tissue containing nitrotyrosine in the lung and spinotrapezius microcirculation. NO: Fine and nano-TiO ₂ significantly and dose-dependently decreased stimulated NO production in isolated microvessels. NO production was increased by radical scavenging with TEMPOL and catalase or NADPH oxidase with apocynin, and was largest in the fine TiO ₂ group. |

| Reference: Okayama et al. (2006, 156824) Species: Rat Cell Type: Ventricular Cardiac Myocytes from Wistar Rats, approximately 3d old | DEP (Tsukuba, Japan) DEPE: 5g of DEP in 5 mL PBS containing 0.05% Tween 80. Others: Catalase, LDH, MPG and SOD. Particle Size: DEP mass median diameter: 0.34 μm . | Route: In Vitro Dose/ Concentration: DEPE: 0-100 $\mu\text{g/mL}$; MPG: 0-1 mM; SOD: 800 U/mL; Catalase: 500 U/mL Time to Analysis: Long-Term Exposure to DEPE: cells were incubated for 24 or 48h. Short-Term Exposure to DEPE: 1, 2, 4, or 8 h and then medium containing DEPE was replaced by serum-free medium, and incubated for an additional 24 h. LDH Activity of Supernatant: 24 h post-DEPE exposure. SOD, Catalase, MPG on DEPE-induced Toxicity: SOD, catalase or MPG was added to cells w/ or w/o DEPE & incubated for 4 or 24h. Medium then replaced w/serum-free & cells incubated for another 24h to analysis. | Cytotoxic Effects of DEPE on Cardiac Myocytes: DEPE above 20 $\mu\text{g/mL}$ damaged cardiac myocytes in a time and concentration-dependent manner in both long- and short-term exposure conditions. However damage was greater after long-term exposure. LDH activity showed a concentration-dependent increase at higher levels of exposure (greater than 20 $\mu\text{g/mL}$). Effects of ROS Scavenging Enzymes and Antioxidant on DEPE-induced Cell Damage: SOD or catalase attenuated 50 $\mu\text{g/mL}$ DEPE-induced cell damage compared with DEPE-treated groups lacking antioxidant enzymes. Co-incubation with SOD and catalase showed more protective effects towards DEPE-induced cell damage, although these effects were not statistically significant from cells treated with SOD only. MPG attenuated 50 $\mu\text{g/mL}$ DEPE-induced cell damage in a concentration-dependent manner in both long and short-term exposure conditions. Especially in long-term exposure MPG showed strong protective effects against DEPE-induced cell damage. Cell viability was not affected by SOD, catalase, or MPG. |
| Reference: Proctor et al. (2006, 088480) Species: Rat Gender: Male Age: 12wks Use: Thoracic Aorta from cp/cp and +/- Male Rats cp/cp = homozygous for cp gene. Prone to obesity and insulin resistant. +/? = heterozygous for either +/-cp or +/+. Lean and metabolically normal. | ROFA from Birmingham, AL Particle Size: 1.95 \pm 0.18 μm aerodynamic diameter of ROFA | Route: Protocol 1: Used two aorta rings per each experimental treatment group (4 groups total). Protocol 2: Used four rings. Dose/Concentration: Protocol 1: exposed to 12.5 $\mu\text{g/mL}$ ROFA-L (at 10mg/mL). Protocol 2: exposed to 1.56, 3.25, 6.26, 12.5 $\mu\text{g/mL}$ ROFA-L (at 10mg/mL). Time to Analysis: Protocol 1: Cells treated with 12.5 $\mu\text{g/mL}$ ROFA-L and/or 104mol/L L-NAME for 20min Protocol 2: Parameters measured after ROFA-L only treatment Contractile response to phenylephrine (PE) was measured | ROFA-L (12.5 $\mu\text{g/mL}$) increased PE-mediated contraction in obese, but not in lean rat aortae. Effect was exacerbated by L-NAME, and it reduced ACh-mediated relaxation in obese and lean aortae. Initial exposure of aortae to ROFA-L caused a small contractile response, which was markedly greater on second exposure in the obese aortae but marginal in lean. |
| Reference: Radomski A et al. (2005, 091377) Species: Rat Strain: Wistar-Kyoto Use: Vascular Thrombosis | Carbon Nano Particles (CNPs) (purchased from SES Research, Houston, TX): Multiplewall Nanotubes (MWNT); Singlewall Nanotubes (SWNT); C60 Fullerenes (C60CS); Mixed Carbon Nanoparticles (MCN) PM: (SRM1648) (NIST) Particle Size: CNPs: NR; PM: 1.4 μm average size | Route: Simultaneous single PM injection into femoral vein as FeCl ₃ injected to induce carotid thrombosis Dose/Concentration: 0.5 mL suspension of 50 $\mu\text{g/mL}$ of PM in 0.9% NaCl solution. Time to Analysis: Blood flow continuously monitored for 900 seconds. | Vascular Thrombosis: FeCl ₃ induced carotid artery thrombosis and MCN had an amplifying effect in the development of thrombosis. Infusions of MCN, SWNT, and MWNT significantly accelerated the time and rate of development of carotid artery thrombosis in rats. SRM1648 was less effective than CNPs in inducing thrombosis, while C60CS exerted no significant effect on the development of vascular thrombosis. |
| Reference: Radomski A et al. (2005, 091377) Species: Human Cell Types: Platelets Use: Human platelet aggregation | Carbon Nano Particles (CNPs) (purchased from SES Research, Houston, TX): Multiplewall Nanotubes (MWNT); Singlewall Nanotubes (SWNT); C60 Fullerenes (C60CS); Mixed Carbon Nanoparticles (MCN); PM (SRM1648) Particle Size: CNPs: NR; PM: 1.4 μm average size | Route: Cell Culture (2.5X10 ⁸ platelets/mL) Dose/Concentration: CNPs: 0.2-300 $\mu\text{g/mL}$; PM: 5 - 300 $\mu\text{g/mL}$ Time to Analysis: Prostacyclin (PGI ₂), S-nitroso-glutathione (GSNO), aspirin, 2-methylthio-AMP, phenanthroline, EDTA and Go6976 were pre-incubated w/ platelets for 1 min before particle addition. Particles added to platelets and platelet aggregation studied for 8min. | Platelet Aggregation: All CNPs, except C60CS, stimulated platelet aggregation (MCN \geq SWNT > MWNT > SRM1648). All particles resulted in upregulation of GPIIb/IIIa in platelets. In contrast, particles differentially affected the release of platelet granules, as well as the activity of thromboxane-, ADP, matrix metalloproteinase- and protein kinase C-dependent pathways of aggregation. Particle-induced aggregation was inhibited by prostacyclin and GSNO, but not by aspirin. |

| Reference: Reed MD et al. (2008, 156903) Species: Rat Gender: Male, Female Strain: CDF (F344)/CrIBR, SHR Age: NR Weight: NR | GEE (two 1996 General Motors 4.3-L V-6 engines; regular, unleaded, non-oxygenated, non-reformulated Chevron-Phillips gasoline, U.S. average consumption for summer 2001 and winter 2001-2002) Particle Size: MMAD: 150nm | Route: Inhalation Exposure Chamber Dose/Concentration: PM: Low- $6.6 \pm 3.7 \mu\text{g}/\text{m}^3$, Medium- $30.3 \pm 11.8 \mu\text{g}/\text{m}^3$, High- $59.1 \pm 28.3 \mu\text{g}/\text{m}^3$ Time to Analysis: 2wk quarantine period in chamber. Exposed 6h/d, 7d/wk, 3d-6m. SHR: surgery to implant telemeter in peritoneal cavity. 4wks recovery. ECG data obtained every 15min beginning 3d preexposure, 7d exposure, 4d postexposure. | Organ Weight: At 6m exposure, the heart weights of male and female rats increased and male rats' seminal vesicle weight decreased. Histopathology: PM-containing macrophages increased by 6m. Serum Chemistry: Serum alanine aminotransferase, aspartate aminotransferase, and phosphorus decreased in medium and high-exposure females. Hematology, Clotting Factors: Hematocrit, red blood cell count, and hemoglobin dose-dependently increased for both genders at both time points. Plasma fibrinogen increased at 1wk in males. Lung DNA Damage: Hypermethylation occurred in medium- and high-exposure male rats at 6m. BAL: For both genders in the high-exposure group, LDH and MIP-2 significantly increased at 6m. ROS decreased at 1wk and 6m. Generally, the production of hydrogen peroxide and superoxide decreased in the high-exposure group and medium- and high-exposure groups, respectively. CV effects in SHR: Lipid peroxides were significantly increased in males in the high exposure group. TAT complexes decreased in females in the high exposure group. Removal of Emission PM: The removal of emission PM strongly linked PM to increased seminal vesicle weight, red blood cell counts, LDH, lipid peroxides, and methylation. |
| Reference: Rhoden et al. (2005, 087878) Species: Rat Gender: Male Strain: Sprague-Dawley Age: Adult Weight: 300g | Urban Ambient Particles (UAPs): SRM-1649; CAPs (from Boston, MA) Particle Size: NR | Route: UAPs: IT Instillation. CAPs: Inhalation Dose/Concentration: UAPs: 750 μg suspended in 300 μl saline; CAPs: 700 \pm 180 $\mu\text{g}/\text{m}^3$ Time to Analysis: UAPs: 30min post-instillation. CAPs: immediately after 5h exposure period | Oxidative Stress and HR Function: UAPs instillation led to significant increases in heart oxidants. HR increased immediately after exposure and returned to basal levels over the next 30 min. SDNN was unchanged immediately after exposure, but significantly increased during the recovery phase. Role of ROS in Cardiac malfunction: Rats were treated with 50 mg/kg NAC 1h prior to UAPs instillation or CAPs inhalation. NAC prevented changes in heart rate and SDNN in UAPs-exposed rats. Role of the Autonomic Nervous System in PM-induced Oxidative Stress: Rats were given 5 mg/kg atenolol, 0.30 mg/kg glycopyrrolate, or saline immediately before CAPs exposure. Both atenolol and glycopyrrolate effectively prevented CAPs-induced cardiac oxidative stress. |
| Reference: Rivero DH et al. (2005, 088653) Species: Rat Gender: Male Strain: Wistar Age: 3m Weight: ~ 250g | PM _{2.5} , collected from heavy traffic area in Sao Paulo, Brazil. PM _{2.5} Composition (%): S (3.05), As (0.30), Br (0.21), Cl (2.09), Co (2.65), Fe (2.67), La (5.42), Mn (0.64), Sb (0.21), Sc (3.25), Th (8.14) Particle Size: PM _{2.5} | Route: IT Instillation Dose/Concentration: 100 or 500 μg of PM _{2.5} . Time to Analysis: 24h post-instillation | Blood: Total reticulocytes significantly increased at both PM _{2.5} doses, while hematocrit levels increased in the 500 μg group. Quantification of segmented neutrophils and fibrinogen levels showed a significant decrease, while lymphocytes counting increased with 100 μg of PM _{2.5} . Pulmonary vasculature: Significant dose-dependent decrease of intra-acinar pulmonary arteriole lumen/wall ratio was observed in both PM _{2.5} groups. Wet-to Dry Weight Ratio: Significant increase in heart wet-to-dry weight ratio was observed in the 500 μg group. |

| Reference: Rodriguez Ferreira Rivero DH et al. (2005, 088659) Species: Rat Gender: Male Strain: Wistar Age: 3m Weight: ~ 250g | PM _{2.5} , collected from heavy traffic area in Sao Paulo, Brazil. PM _{2.5} Composition (%): S (3.05), As (0.30), Br (0.21), Cl (2.09), Co (2.65), Fe (2.67), La (5.42), Mn (0.64), Sb (0.21), Sc (3.25), Th (8.14) Particle Size: PM _{2.5} | Route: IT Instillation Dose/Concentration: 50 and 100 µg of PM _{2.5} . Time to Analysis: HR and SDNN were assessed immediately before instillation, 30 and 60min post-instillation. | HR decreased significantly with time, but no significant effect of treatment or interaction between time and treatment was observed. In contrast, there was a significant SDNN interaction between time and treatment. The SDNN decreased 60 min after instillation with PM _{2.5} concentration of 50 and 100 µg. |
| Reference: Seagrave et al. (2008, 191990) Species: Rat Gender: Male Strain: SD Age: 10-12wks Weight: 250-300g | GEE (2 1996 General Motors 4.3-L V6 gasoline engines; conventional Chevron Phillips gasoline, U.S. average composition) (CO, NO, NO ₂ , SO ₂ , THC) (PM _{2.5} composition- EC, OC, SO ₄ , NH ₄ , NO ₃) Simulated downwind coal emission atmospheres (SDCAs) (fly ash, gas-phase pollutants, sulfate aerosols, NO, NO ₂ , SO ₂) Paved Road Dust (RD) (Los Angeles, CA; New York City, NY; Atlanta, GA) Particle Size: GEE: MMAD- 150nm, RD: 2.6 ± 1.7 µm, SDCA: 0.1-1.0 µm | Route: Nose-only Inhalation Dose/Concentration: GEE: 60 µg/m ³ , SDCAs: 317-1072 µg/m ³ , RD: 306-954 µg/m ³ ; GEE: CO- 104ppm, NO- 16.7ppm, NO ₂ - 1.1ppm, SO ₂ - 1.0ppm, THC- 12ppm; SDCAs: CO- < 1ppm, NO- 0.19-0.62ppm, NO ₂ - 0.10-0.37ppm, SO ₂ - 0.07-0.24ppm, THC- < 1ppm Time to Analysis: Quarantined 2wks. 6h exposure then ip injected. Cannula ligated into trachea and connected to rodent ventilator. Thorax and abdomen opened. Killed after measurements taken. | GEE produced CL in the lungs, heart, and liver. RD produced a significant effect in the heart at the low dose. SDCAs had no effect on CL. RD significantly increased the heart's oxidative stress, as demonstrated by the TBARS levels. GEE did not affect the amount of macrophages or PMN. SDCAs increased macrophages. The RD low dose increased macrophages and PMN. SDCAs increased P _{enth} values and tidal volumes. |
| Reference: Simkhovich et al. (2007, 096594) Species: Rat Gender: Female Strain: Fischer 344 x Brown Norway hybrid Age: 4, 26 m Use: Study performed in isolated Langendorff-perfused rat hearts | Ultra Fine Particles (UFPs) isolated from industrial diesel reference PM 2975 Particle Size: UFPs □ 0.1 µm | Route: Heart Perfusion (ex-vivo) Dose/Concentration: UFPs 12.5, 25, and 37.5 mg. Time to Analysis: Hearts perfused w/ UFPs for 30 minutes and analysis conducted every 10min. | Young adult and old hearts demonstrated equal functional deterioration in response to direct infusion of UFPs. Developed pressure in young adult UFPs-treated hearts fell from 101 ± 4 to 68 ± 8 mmHg. In the old UFPs-treated hearts developed pressure fell by 35%. Positive dP/dt was equally affected in the young adult and old UFPs-treated hearts and was decreased by 28% in both groups. |
| Reference: Sun Q et al. (2005, 186814) Species: Mouse Gender: Male Strain: ApoE ^{-/-} Age: 16wks | CAPs: PM _{2.5} from Tuxedo, NY. HFCD: High Fat Chow Diet NCD: Normal Chow Diet Particle Size: PM _{2.5} | Route: Whole-body Inhalation Dose/Concentration: PM _{2.5} : 85 µg/m ³ ; Daily concentration: 10.6 (SD 3.4) µg/m ³ (mean) Average exposure over 6 mth period: 15.2 µg/m ³ . Time to Analysis: Study diets fed for at least 10wk prior to exposure to PM _{2.5} or FA. Exposed for 6h/d, 5d/wk for 6m. Sacrificed 15-47d after exposure. | Vasomotor Function: Mice fed HFCD and exposed to PM _{2.5} demonstrated an increase in the half-maximal dose for dilation to ACh with no changes in peak relaxation compared to the mice exposed to FA and fed HFCD and NCD. Atherosclerosis Burden with PM_{2.5}: In vivo MRI imaging of atherosclerosis burden in the abdominal aorta revealed significantly increased plaque burden in the mice fed HFCD compared with the mice fed NCD. Mean (SD) plaque areas in the mice exposed to PM _{2.5} and fed HFCD vs. mice exposed to FA and fed HFCD were 33 (10) vs. 27 (13) units, respectively. PM_{2.5} and Vascular Inflammation: A 2.6-fold higher inducible NOS content was apparent in the mice exposed to PM _{2.5} and fed HFCD compared with the mice exposed to FA and fed HFCD chow and a 4-fold increase in the mice exposed to PM _{2.5} and fed NCD compared with the mice exposed to FA and fed NCD. |

| Reference: Sun et al. (2008, 157033) Species: Mouse Gender: Male Strain: ApoE ^{-/-} Age: 6wks | CAPs PM _{2.5} Collected from Sterling Forest State Park, Tuxedo NY (40 miles NW of Manhattan) Particle Size: PM _{2.5} | Route: Inhalation Chamber Dose/Concentration: Average Concentration of: 85 µg/m ³ CAPs in chamber. Average exposure over 6m = 15.2 µg/m ³ . Time to Analysis: 6h/d, 5d/wk for 6m. Mice received two different diets, high-fat chow and normal-chow. | Macrophage and Tissue Factor Expression in Aortic Segments: Tissue Factor (TF) expression was noted predominantly in the extracellular matrix surrounding macrophages, foam cell-rich areas and around smooth muscle cells. 1. High-Fat Diet: Increased TF and increased macrophage infiltration was observed in the plaques of high-fat chow mice exposed to PM compared to mice exposed to air and high fat diet. 2. Normal Diet: PM-exposed mice saw an increase in CD68 expression compared to air-exposed. However TF expression was not significantly different in PM exposed normal diet mice compared to control normal diet mice. |
| Reference: Sun et al. (2008, 157033) Species: Human Cell Lines: Human Bronchial Epithelial Cells (BEAS-2B); Vascular Smooth Muscle Cells (hSMCs); and Monocytes (THP-1) | Ambient Particles collected from Sterling Forest State Park, Tuxedo, NY (24 h/d for 4wks) Particle Size: Particle size ranges: 1. < 0.18 µm 2. 1.8 - 2.5 µm or 3. 2.5 - 10 µm | Route: In vitro Dose/Concentration: 10-300 µg/ml Time to Analysis: Doses were tested for durations up to 24 h. | Dose durations tested for up to 24-h did not indicate detectable effects on cell viability. Effect of PM on TF Expression and Activity in hSMCs: In the PM size range of 1-3 µm, significant increases in TF expression was observed at doses of 100 and 300 µg/mL. In the < 0.18 µm size range, significant increase in TF expression was observed at all doses. The particles with sizes 0.18 - 1.0 µm did not induce significant change in TF expression. Effect of PM on TF Expression and Activity in Monocyte Cells: TF protein expression increased with < 0.18 µm and the 1-3 µm range particles. Expression was increased in the 0.18-1.0 µm particle range but it was limited compared to the other PM size ranges. In general TF expression was higher in monocytes than in hSMCs cells, but not significantly. Effect on TF Expression and Activity in Bronchial Epithelial Cells: 100 µg/mL of the 1-3 µm and < 0.18 µm particles significantly increased TF expression. TF mRNA Expression: TF mRNA was increased rapidly within the first hour in response to SRM-1694a PM. The lowest dose of SRM PM ₁₀ µg/mL induced highest levels of mRNA in hSMCs, no further increase was observed at higher concentrations. |
| Reference: Sun et al. (2008, 157032) Species: Rat Gender: Male Strain: Sprague-Dawley Age: 500-650g | PM _{2.5} , Ultra Fine Particle (UFP) or FA Particle Size: PM _{2.5} ; UFP: < 0.1 µm | Route: Inhalation via Whole-body Exposure Dose/Concentration: Mean PM _{2.5} concentration: 79.1 ± 7.4 µg/m ³ . Normalized PM _{2.5} over 10wk period: 14.1 µg/m ³ . Time to Analysis: 6h/day, 5d/week random exposure to PM _{2.5} , UFP, or FA for a total of 10 weeks. At the end of week 9 exposure, rats were infused w/ 0.75 mg/kg/d of All for 7 days. PM _{2.5} , UFP, or FA, continued during All infusion period. All = angiotensin II | Mean Arterial Pressure (MAP): after All infusion, MAP was significantly higher in PM _{2.5} -All vs. FA-All group. Aortic Vasoconstriction to PE was potentiated with exaggerated relaxation to the Rho-kinase (ROCK) inhibitor Y-27632 and increase in ROCK-1 mRNA levels in the PM _{2.5} -All group. Superoxide production in the aorta was increased in the PM _{2.5} . All group compared to FA-All group, inhabitable by apocynin and L-NAME with coordinate upregulation of NAD(P)R oxidase subunits p22phox and p47phox and depletion of tetrahydrobiopterin. |
| Reference: Sun et al. (2008, 157032) Species: Rat Gender: Male Strain: Sprague-Dawley Age: 500-650g Use: Primary Rat Aortic Smooth Muscle Cells (RASMCs), passages 4 to 8 used for the experiment. | PM _{2.5} , Ultra Fine Particle (UFP) or Filtered Air (FA) Particle Size: PM _{2.5} ; UFP: < 0.1 µm | Route: Cell Culture Dose/Concentration: UFP, PM _{2.5} : 10 or 50 µg/mL; All: 100 nmol/L Time to Analysis: Exposed to UFP or PM _{2.5} and parameters measured at 0, 1, 3, 6, and 15min. All = angiotensin II | Exposure to UFPs and PM _{2.5} was associated with an increase in ROCK activity, phosphorylation of myosin light chain, and MYPT1. Pretreatment with N-Acetylcysteine and the Rho kinase inhibitors (Fasudil and Y-27632) prevented MLC and MYPT-1 phosphorylation by UFPs suggesting a Superoxide-mediated mechanism for PM _{2.5} and UFPs effects. |

| Reference: Sun Q et al. (2009, 190487) Species: Mouse Gender: Male Strain: C57BL/6, c- <i>fms</i> ^{YFP} (transgenic, yellow fluorescent protein under monocyte-specific promoter) Age: 8, 10wks Weight: NR | PM (concentrated- northeastern regional background; Tuxedo Park, NY) Particle Size: Diameter: 2.5 μ m | Route: Whole-body Exposure. IT Instillation. Dose/Concentration: Exposure chamber (mean): 72.7 μ g/m ³ , IT: 1.6mg/kg Time to Analysis: C57BL/6 mice equilibrated 2wks, fed high-fat chow 10wks. Exposed in vivo 6h/d, 5d, 128d. <i>fms</i> ^{YFP} rendered diabetic or fed normal chow 10wks. IT instilled with PM 5min, 2X/wk, 10wks. | Metabolic Impairment: PM induced insulin, homeostasis model assessment indexes, elevated glucose, and abnormalities in lipid profile consistent with the IR phenotype. Vascular Endothelium: PM decreased peak relaxation and ED ₅₀ to ACH and peak relaxation to insulin. Lower levels of NO release were seen. Insulin Signaling: PM reduced the phosphorylation of Akt in intact aorta. PKC- β 11 was the only PKC isoform to increase. Adipose Inflammation, Visceral Adiposity: PM significantly increased TNF- α , IL-6, E-selectin, ICAM-1, plasminogen activator inhibitor-1, and retin. PM increased visceral and mesenteric fat mass. F4/80 ⁺ macrophages in fat tissue and adipocyte size increased. PM downregulated IL-10 and galactose-N-acetylgalactosamine-specific lectin. YFP Cell Adhesion and Infiltration: PM increased YFP cells in the adipose tissue, YFP cell infiltration in the mesenteric fat, and YFP cell adhesion to endothelium. |
| Reference: Tamagawa et al. (2008, 191988) Species: Rabbit Gender: Female Strain: New Zealand White Age: 12wks Weight: Acute (average)- 2.4 \pm 0.2kg, Chronic (average)- 2.7 \pm 0.3kg | PM ₁₀ (urban; Ottawa, Canada) Particle Size: Mean diameter: 0.8 \pm 0.4 μ m | Route: Intrapharyngeal Instillation Dose/Concentration: Acute- 2.6mg/kg, Chronic- 2mg/kg Time to Analysis: Acute animals exposed days 1, 3, 5. Chronic animals exposed 2x 4wks. Killed postexposure. | Inflammation: PM ₁₀ induced more macrophages, AMs, positive and activated AMs, and fewer tissue macrophages. NO, WBC and PMN were only significantly higher in the first two weeks and IL-6 in the first week. Vascular endothelial function: PM ₁₀ significantly reduced Ach-stimulated relaxation and did not alter SNP-stimulated relaxation. A significant inverse relationship between IL-6 and Ach-induced relaxation occurred at week 1 in the acute model and weeks 1 and 2 in the chronic model. AMs: The chronic model had a significant correlation between IL-6 and both positive and activated AMs at week 1. A significant inverse relationship occurred between Ach and both the volume fraction of positive and activated AMs. |
| Reference: Tankersley et al. (2008, 157043) Species: Mouse Gender: Male Strain: C57BL/6, C3H/HeJ, B6C3F1 Age: 18, 28m Weight: NR | Carbon black (CB) (Wright dust feed particle generator – BGI, Waltham, MA) Particle Size: 0.1-1.0 μ m | Route: Inhalation Chamber Dose/Concentration: Average PM _{2.5} concentration- 401 \pm 46 μ g/m ³ , Average PM ₁₀ concentration- 553 \pm 49 μ g/m ³ Time to Analysis: Exposed 3h/d 4d. | Hemodynamics: CB significantly elevated right atrial and ventricular pressures, pulmonary arterial pressure and vascular resistance, all of which were more pronounced in the 28m-old mice. RV contractility (specifically, the ejection fraction and maximum change in pressure over time) reduced in CB-exposed 28m-old mice. Heart tissue: CB significantly declined Ca ²⁺ -dependent NOS activity and was more pronounced in 28m-old mice, who also had NOS2 upregulated. CB enhanced ROS generation and NOS-uncoupling and was greatest in 28m-old mice. CB also increased MMP2, MMP9, ANP, BNP, which were greatest in 28m-old mice. CB also reduced PKG-1 in 28m-old mice. |

| Reference: Tankersley et al. (2007, 097910) Species: Mouse Gender: Male Strain: C3H/HeJ and C57BL/6J Age: 10wks Weight: 22-26g | Carbon Black (CB) and Filtered Air (FA) Particle Size: CB: 2.4 μm (MMAD) (GSD 2.75 μm). | Route: CB: Whole-body Inhalation Chamber; Sympathetic (S) & Parasympathetic (PS) blockade: IP Injection Dose/Concentration: CB: $159 \pm 12 \mu\text{g}/\text{m}^3$; PS (atropine): 0.5mg/kg; S(propranolol): 1mg/kg Time to Analysis: Successive 3h CB and FA Exposures: conducted from 9 a.m. to 1 p.m., or at least 3h after dark-to-light transition (exposure period selected based on the nadir in circadian pattern in HR responses). Subgroups of both strains exposed to PS & S blockade. | FA Exposure with Saline: A significantly greater 3 h average response occurred in C3 compared with B6 mice. PS Blockade: No evident strain difference between C3 and B6 was observed. S Blockade: 3 h average HR responses for C3 mice were significantly reduced compared with saline. CB Exposure: HR responses were significantly elevated in C3 compared with B6 mice, but these HR responses were not different relative to FA exposure. S Blockade: HR was significantly elevated in B6 mice during CB relative to FA, but was not changed in C3 mice. |
| Reference: Tankersley CG et al. (2004, 094378) Species: Mice Strain: AKR/J Age: ~ 180d Use: Age matched animals | Carbon Black (CB) and Filtered Air (FA) Particle Size: CB: 0.1 to 1 μm . | Route: Whole-body Inhalation Dose/Concentration: CB average concentration: $160 \pm 22 \mu\text{g}/\text{m}^3$ Time to Analysis: FA exposure on day 1, CB exposure 3h/d for 3 consecutive days (days 2-4) | On day 1, HR was significantly depressed during FA in terminally senescent mice. By day 4, HR had significantly slowed due to the effects of 3 days CB exposure. The combined effects of terminal senescence and CB exposure acted to depress HR to an average (\pm SEM) 445 ± 40 bpm, ~ 80 bpm lower compared to healthy HR responses. The change in rMSSD was significantly greater on day 1 and day 4 in terminally senescent mice, compared to healthy mice. LF/HF ratio was significantly depressed in terminally senescent mice on day 1. By day 4, significant increases in LF/HF were evident in healthy mice during CB exposure. Terminally senescent mice modulated a lower HR without change in the LH/HF ratio during CB exposure. |
| Reference: Thomson et al. (2005, 087554) Species: Rat Gender: Male Strain: Fischer-344 Weight: 200-250g | Urban Ambient Particles (EHC-93) from Ottawa, Canada; Ozone Particle Size: Respirable Modes (aerodynamic diameter): 1.3 and 3.6 μm . Non-respirable Mode (aerodynamic diameter): 15 μm | Route: Nose-only Inhalation Dose/Concentration: EHC-93: 0, 5, 50 mg/m^3 ; Ozone: 0, 0.4, 0.8ppm Time to Analysis: 4h to particles, ozone, or combination of particles and ozone. | Both pollutants individually increased preproET-1, ET-1 and endothelial NOS mRNA levels in the lungs shortly after exposure, consistent w/ the concomitant increase in plasma of ET-1[1-21]. Prepro-ET1 mRNA remained elevated 24 h post-exposure to particles but no after ozone. Both pollutants transiently increased ET-B receptor mRNA expression, while ozone decreased ET-A receptor mRNA levels. Coexposure to particles plus ozone increased lung preproET-1 mRNA but not plasma ET-1[1-21], suggesting alternative processing or degradations of endothelins. This coincided w/ an increase of MMP-2 in the lungs (this enzyme cleaves bigET-1 to ET-1[1-32]). |
| Reference: Thomson E et al. (2006, 097483) Species: Rat Gender: Male Strain: Fischer-344 Weight: 200-250g | Urban Ambient Particles (EHC-93) from Ottawa, Canada; Ozone Particle Size: NR | Route: Nose-only Inhalation Dose/Concentration: EHC-93: 0, 50 mg/m^3 ; Ozone: 0, 0.8ppm Time to Analysis: 4h to particles, ozone, or combination of particles and ozone. Sacrificed immediately following exposure or following 24h recovery. | Circulating levels of both ET-1[1-21] and ET-3[1-21] were increased immediately after exposure to PM and ozone. While expression of preproET-1 mRNA in the lungs increased, expression of preproET-3 mRNA decreased immediately after exposure. PreproET-2 mRNA was not detected in the lungs, and exposure to either pollutant did not affect plasma ET-2 levels. Coexposure to ozone and particles, while altering lung preproET-1 and preproET-3 mRNA levels in a fashion similar to ozone alone, did not cause changes in the circulating levels of the two corresponding peptides. |

| Reference: Totlandsdal et al. (2008, 157056) Species: Rat Gender: Male Strain: WKY/NCrl and Crl: WI (Han) Age: Adult Weight: 220-300 g, WKY/NCrl; 250-300 g, Crl: WI (Han) Use: Isolation of Primary Rat Epithelial Lung Cells (PRELCs): from WKY/NCrl rats. Isolation of Rat Ventricular Cardiomyocytes and Cardiofibroblasts (RVCMs and RVCFBs) from Crl: WI (Han) rats. | Pigment Black Printex 90 (Frankfurt, Germany); PM: SRM 1648 Particle Size: Printex 90: 12-17nm; PM: NR | Route: Cell Culture Dose/Concentration: Printex 90: 0, 50, 100, 200 or 400 µg/mL; PM: 0, 200 µg/mL Time to Analysis: 20h | Lung cell cultures: Both particles induced release of IL-6 and IL-1 β, whereas TNF α was only detected upon exposure to PM. Cardiac Cell Cultures: IL-6 release was strongly enhanced upon exposure to conditioned media, and markedly exceeded the response to direct particle exposure. IL-1, but not TNF-α, seemed necessary, but not sufficient, for this enhanced IL-6 release. The role of IL-1 was demonstrated by use the use of an IL-1 receptor antagonist that partially reduced the effect of the conditioned media, and by a stimulating effect on the cardiac cell release of IL-6 by exogenous addition of IL-1 α and IL-1 β. |
| Reference: Tzeng H-P et al. (2007, 097883) Species: Rat Strain: Wistar Cell Type: Primary Vascular Smooth Muscle Cell Culture (VSMCs): isolated from thoracic aortas from 200-250g rats. | Motorcycle Exhaust Particulate Extract (MEPE) collected from a Yamaha motorcycle with a 50 cm ³ two-stroke engine using 95% octane unleaded gasoline. Particle Size: PM ₁ , PM _{2.5} , PM ₁₀ | Route: In vitro Dose/Concentration: 10-100 µg/mL Time to Analysis: 3d | Exposure of VSMCs to MEPE (10-100 µg/mL), enhanced serum-induced VSMC proliferation. The expression of proliferating cell antinuclear antigen was also enhanced in the presence of MEPE. VSMCs treated with MEPE induced increase COX-2 mRNA, protein expression, and PGE2 production, whereas the level of COX-1 protein was unchanged. MEPE increased the production of ROS in VSMCs, in a dose-dependent manner. MEPE triggered time-dependent ERK1/2 phosphorylation in VSMCs which was attenuate by antioxidants (NAC, PTDC). The level of translocation of NF-kappaB-p65 in the nuclei of VSMCs was also increased during MEPE exposure. The potentiating effect of MEPE in serum-induced VSMC proliferation was abolished by COX-2 selective inhibitor NS-398, specific ERK inhibitor PD98059, and antioxidants (NAC, PTDC). |
| Reference: Tzeng H-P et al. (2003, 097247) Species: Rat Strain: Wistar Cell Type: Primary Vascular Smooth Muscle Cell Culture (VSMCs) | Motorcycle Exhaust Particulate Extract (MEPE) collected from a Yamaha motorcycle with a 50 cm ³ two-stroke engine using 95% octane unleaded gasoline. Particle Size: NR | Route: In vitro Dose/Concentration: MEPE: 10 µg/mL; Nifedipine: 10 µmol; Manganese Acetate: 100 µmol; Staurosporine: 1-2 nM; Chelerythrine: 1 µM Time to Analysis: 18h | MEPE induced a concentration-dependent enhancement of vasoconstriction elicited by phenylephrine in the organ cultures of intact and endothelium-denuded aortas for 18h. Nifedipine, manganese acetate, and staurosporine, but not chelerythrine, inhibited the enhancement of vasoconstriction by MEPE. ML-9 inhibited the enhancement of vasoconstriction by MEPE. MEPE enhanced the phosphorylation of 20k-Da in rat vascular smooth muscle cells. N-acetylcysteine significantly inhibited the enhancement of vasoconstriction by MEPE. A time-dependent increase in ROS production by MEPE was also detected in primary cultures of VSMCs. |

(2008, 159345) Species: Rat Gender: Male Strain: SHR Age: 6m Weight: NR | Ultrafine Carbon Particles (UFCP) Particle Size: Size- 31 ± 0.3 nm, MMAD- 46nm, Surface area concentration- 0.139 m ² (particle)/m ³ (air), Mass specific surface area- 807m ² /g | Route: Whole-body Exposure Dose/Concentration: 172 µg/m ³ Time to Analysis: Acclimatized 2d. 1d baseline. 24h exposure. 4d recovery. Sacrificed 1 st or 3 rd day of recovery. | Cardiophysiology: The mean arterial BP and HR increased but returned to baseline levels by the 4 th recovery day. SDNN and HRV decreased. RMSSD and LF/HF decreased but were not significant. Pulmonary Inflammation: UFCP did not cause pulmonary inflammation. Pulmonary and Cardiac Tissue: HO-1, ET-1, ETA, ETB, TF, PAI-1 significantly increased in the lung on the 3 rd recovery day. HO-1 was repressed in the heart, but the other markers had slight, nonsignificant increases. Systemic Responses: Neutrophil and lymphocyte cell differentials significantly increased on the 1 st recovery day. Other blood parameters were unaffected. The plasma renin concentration increased on the first 2 recovery days. Ang I and II concentrations increased on the 1 st recovery day but was not significant. |
| Reference: Wallenborn et al. (2008, 191171) Species: Rat Gender: Male Strain: Wistar Kyoto (WKY) Age: 13wks Weight: NR | Zinc Sulfate (ZnSO ₄ , aerosolized) Particle Size: NR | Route: Nose-only Inhalation Dose/Concentration: 9.0 ± 2.1 µg zinc/m ³ , 35 ± 8.1 µg zinc/m ³ , 123.2 ± 29.6 µg zinc/m ³ Time to Analysis: Exposed 5h/d, 3d/wk, 16wks. Half of the rats used for plasma/serum analysis, other half for isolation of cardiac mitochondria. | A trend toward increased BALF protein was seen. Cardiac mitochondrial ferritin had a small, significant increase. Mitochondrial succinate dehydrogenase and glutathione peroxidase had small, significant decreases. Subchronic exposure to 100 µg/m ³ caused expression changes of cardiac genes involved with cell signaling events, ion channels regulation, and coagulation. No pulmonary-related effects were seen. |
| Reference: Wellenius GA et al. (2003, 055691) Species: Dog Gender: Female Strain: Mixed mongrel Age: NR Weight: 14-17kg | CAPs Particle Size: 0.26 ± 0.04 µm | Route: Permanent Tracheostomy Dose/Concentration: Median: 285.7 µg/m ³ , Range: 161.3-957.3 µg/m ³ Time to Analysis: Thoracotomy and tracheostomy performed. 5-13wks recovery. Pairs of subjects: exposed 6h/d either 2 nd or 3 rd exposure time and filtered air other days. 5min preconditioning occlusion. 20min rest interval. 5min experimental occlusion. Some dogs exposed 6h/d, 4d (consecutive), filtered air on day 4. | CAPs increased the ST-segment elevation and remained elevated 24h after exposure. This increase was seen in precordial leads V ₄ and V ₅ . Multivariate regression analyses showed that the mass concentration of Si was significantly associated with the peak ST-segment elevation and integrated ST-segment change. Univariate regression analyses showed Pb to also be significantly associated with these measures. CAPs had no effect on peak heart rate during occlusion or the maximum occlusion-induced increase in heart rate. |
| Reference: Wellenius GA et al. (2004, 087874) Species: Rat Gender: Male Strain: Sprague-Dawley Age: Adult Weight: ~ 250 g Use: Rat Model for Acute Myocardial Infarction (AMI): Left-ventricular MI induced by thermocoagulation. Animals allowed to recover for at least 12h after surgery. | CAPs; CO Particle Size: CAPs: PM _{2.5} | Route: Whole-body Inhalation Chambers Dose/Concentration: CO: 35ppm; CAPs (median concentration): 350.5 µg.m ³ ; CAPs + CO: (CAPs median concentration): 318.2 µg/m ³ Time to Analysis: 1h exposure to CAPs or CAPs + CO for 1h. Exposure to pollutants was preceded and followed by 1h exposure to FA. Exposure experiments were performed during the period of 07/2000 and 01/2003 | CO exposure reduced the ventricular premature beat (VPB) frequency by 60.4% during the exposure time compared to controls. This effect was modified by both infarct type and the number of pre-exposure VPBs, and was mediated through changes in hear rate (HR). Overall, CAPs exposure increased VPB frequency during the exposure period, but this did not reach statistical significance. This effect was modified by the number of pre-exposure VPBs. In rats with a high number of pre-exposure VPB, CAPS exposure significantly decreased VPB frequency (67.1%). Overall, neither CAPs nor CO had any effect on HR, but CAPs increased HR in specific subgroups. No significant interactions were observed between the effects of CO and CAPs. |

| Reference: Wellenius et al. (2006, 156152) Species: Rat Gender: Male Strain: Sprague-Dawley Age: Adult Weight: ~ 250g Use: Rat Model for Acute Myocardial Infarction (AMI): Left-ventricular MI induced by thermocoagulation. Animals allowed to recover for at least 12h after surgery. | CAPs (Boston, MA) Particle Size: CAPs: PM _{2.5} | Route: Whole-body Inhalation Chambers Dose/Concentration: CO: 35ppm; CAPs (median concentration): 645.7 µg.m ³ ; CAPs + CO: 37.9ppm Time to Analysis: CAPs or CAPs + CO exposure for 1h. Exposure to pollutants was preceded and followed by 1h exposure to FA. | Among rats in the CAPs group, the probability of observing supraventricular arrhythmias (SVA) decreased from the baseline to exposure and post-exposure periods. The pattern was significantly different than that observed for the FA group during the exposure period. In the subset with one or more SVA during the baseline period, the change in SVA rate from baseline to exposure period was significantly lower in the CAPs and CO groups only, when compared to the FA group. No significant effects were observed in the group simultaneously exposed to CAPs and CO. |
| Reference: Wichers et al. (2004, 055636) Species: Rat Gender: Male Strain: SH Age: 75d | HP-12 (oil-combustion derived PM obtained from inside wall of a Boston power plant stack burning residual oil (number 6)). Water-leachable constituents (µg/mg): SO ₄ (217.3); Zn (11.4); Ni (6.9); Fe (0.0); V (1.3); Cu (0.2); Pb (0.0) 1M HCl-leachable constituents (µg/mg): SO ₄ (220.6); Zn (15.5); Ni (14.8); Fe (15.6); V (32.9); Cu (1.1); Pb (1.7) Particle Size: 3.76 µm (MMAD) (GSD 2.16) | Route: IT Instillation Dose/Concentration: HP-12 (mg/kg): 0.00 (saline control), 0.83 (low), 3.33 (mid), 8.33 (high) Time to Analysis: Single-dose Sacrificed 96h or 192h post-IT. | Exposures to mid and high-dose HP-12 induced large decreases in HR, BP, and body temperature. The decreases in HR and BP were most pronounced at night and did not return to pre-IT values until 72h (HR) and 48h (BP) after dosing. ECG abnormalities (rhythm disturbances, bundle branch block) were observed primarily in the high dose group. |
| Reference: Wold et al. (2006, 097028) Species: Rat Gender: Female Strain: Sprague-Dawley Use: L jugular vein and R carotid artery were cannulated. | UFPs from either ambient air (UFAAs) or diesel engine exhaust (UFDGs); UFDs from industrial forklift exhaust and soluble fraction UFID suspension, particle free (SF-UFID) Particle Size: UFAAs diameter □ 150 nm; UFDGs diameter □ 100nm | Route: IV Infusion (in vivo study) Dose/Concentration: UFDG (50µg/m) Time to Analysis: Infused w/UFAA or UFDG. Monitored continuously for 1h then sacrificed. | Infusion of UFDGs caused ventricular premature beats (VPBs) in 2 out of 3 rats. Ejection fraction increased slightly in rats receiving UFAA and was unchanged in the UFDG and saline groups. |
| Reference: Wold LE et al. (2006, 097028) Species: Rat Gender: Female Strain: Sprague-Dawley Use: Heart Langendorff-perfusion apparatus | UFPs from either ambient air (UFAAs) or diesel engine exhaust (UFDGs); UFDs from industrial forklift exhaust and soluble fraction UFID suspension, particle free (SF-UFID) Particle Size (Distribution): UFAAs diameter; □150 nm; UFDGs diameter: □ 100nm | Route: Langendorff Heart Perfusion (in vitro) Dose/Concentration: UFDG (100 µg /2ml); UFID (12.5 µg/l in perfusate); SF-UFID (12.5 µg/l) Time to Analysis: Langendorff 1: Treated w/UFDG. Langendorff 2: Treated with UFID & SFUFID. Both experiments were monitored continuously for 1h after injection. | UFDGs caused a marked increase in left-ventricular and end-diastolic pressure (LVEDP) after 30 min of exposure. UFIDs caused a significant decrease in left-ventricular systolic pressure (LVSP) at 30min after the start of infusion. This effect was absent when SF-UFID was studied. |
| Reference: Yatera et al. (2008, 157162) Species: Rabbit Gender: Female Strain: WHHL Age: 42wks Weight: 3.2 ± 0.1 kg (avg) | EHC-93 from Ottawa, Canada Particle Size: NR | Route: IT Instillation Dose/Concentration: PM ₁₀ suspension: 5mg EHC-93 in 1ml saline Time to Analysis: Exposed 2x/wk for 4 wks. Acute effects observed at 0.5, 1, 2, 4, 8, 12, and 24h after initial instillation. Chronic effects observed 1x/wk for 4 wks. | Exposure to PM ₁₀ caused progression of atherosclerotic lesions in thoracic and abdominal aorta. It also decreased circulating monocytes expressing high levels of CD31 and CD49d, and increased expression of CD54 (ICAM-1) and CD106 (VCAM-1) in plaques. Exposure to PM ₁₀ increased the number of BrdU-labeled (*) monocytes into plaques and into smooth muscle underneath plaques. (*onocytes labeled with BrdU in donor rabbits were transfused to recipient rabbits as whole blood, and the recruitment of BrdU-labeled cells into vessel walls and plaques in recipients was measured by quantitative histological methodology. |

| Reference: Ying Z et al. (2001, 019011) Species: Mice Gender: Male Strain: ApoE ^{-/-} Age: 16wks | CAPs: PM _{2.5} , New York City (Manhattan), NY; May-Sept 2007 Particle Size: NR | Route: Inhalation Dose/Concentration: 138.4 ± 83.7 µg/m ³ Time to Analysis: 6h/d × 5d/wk × 4m | <p>Vascular tone: Significant decrease in PE-induced maximum contraction of aortic rings in CAPs-exposed mice. No difference in sensitivity to PE between groups. Treatment with the soluble guanylate cyclase inhibitor ODDQ restored the response to PE in CAPs aortic rings. No significant differences in relaxation induced by ACh. CAPs abolished the relaxation induced by Ca ionophore A23187. CAPs exposure slightly (but significantly) decreased maximum relaxation induced by SNP.</p> <p>Protein expression: iNOS mRNA expression was increased in the aortas of CAPs-exposed mice. eNOS and GTPCH levels were unchanged. Distribution of iNOS protein expression was limited to plaque in air-exposed mice and was found in the plaque and media for CAPs-exposed mice.</p> <p>Superoxide production: Superoxide levels in CAPs-exposed mice were increased in the aorta compared to air-exposed mice. The addition of L-NAME significantly increased superoxide production. Extensive protein nitration in aortas of CAPs mice. NADPH subunits Rac1 and p47 phox mRNA expression was increased in aortas of mice exposed to CAPs.</p> <p>Atherosclerosis: Significant increase in plaque area of CAPs-exposed mice. Higher levels of macrophage infiltration, collagen deposition, and lipid composition of plaques from CAPs-exposed mice.</p> |
| Reference: Ying Z et al. (2001, 019011) Species: Mouse Gender: Male Strain: ApoE ^{-/-} Age: 6wks Weight: NR | CAPs (New York, NY) (May-Sept. 2007) Particle Size: Diameter: < 2.5 µm | Route: Exposure Chamber Dose/Concentration: Ambient PM _{2.5} : 23 ± 75.9 µg/m ³ , Chamber PM _{2.5} : 138.4 ± 83.7 µg/m ³ Time to Analysis: Fed high-fat chow 10wks. Exposed 6h/d, 4m. | <p>Vascular: Constriction responses to KCl were similar between CAPs-exposed and control mice. PE-induced maximum contraction significantly decreased in CAPs mice, which was attenuated by the soluble guanine cyclase inhibitor ODDQ. CAPs prevented calcium ionophore A23187-induced relaxation. CAPs decreased SNP-induced maximal relaxation.</p> <p>iNOS, Aortic O₂: iNOS mRNA expression increased. Aortic O₂ increased and was further increased by NOS inhibitor L-NAME.</p> <p>Atherosclerosis: The only NADPH oxidase subunits affected were Rac1 and p47^{phox}, which increased. Atherosclerotic burden in the thoracic aorta, macrophage infiltration, collagen deposition, and lipid composition in the aorta all increased.</p> |
| Reference: Yokota S et al. (2004, 096516) Species: Rat Gender: Male Strain: Sprague-Dawley (IGS) Weight: 345-498.2g | DEP (obtained from the Japan Automobile Research Institute) Particle Size: NR | Route: IT Instillation Dose/Concentration: Group 1: DEP: 1mg/0.1ml Group 2: DEP: 0.2 ml (10, 12.5 or 25 mg/ml) Group 3: DEP 2.5 or 5mg/0.2ml Time to Analysis: DEP pre-treatment 24-72h before ischemia/reperfusion. | <p>DEP effects on myocardial Ischemia/Reperfusion-induced arrhythmia: An increased mortality was observed in the DEP group compared to the vehicle-treated group. 46% of the animals in DEP died during the first 3 min reperfusion period. The animals of other groups were intratracheally instilled with DEP at the beginning of ischemia/reperfusion experiment, or were pretreated with polyethylene glycol-conjugated SOD (1000 IU/kg, iv). In these animals, incidences of both arrhythmia and mortality were similar to those in the animals treated with the vehicle.</p> <p>DEP effects on the biochemical and hematological parameters: Neutrophil count was elevated by a higher dose (5 mg) of DEP at 24 h after the IT instillation, and oxygen radical production, which was induced by 12-O-tetradecanoylphorbol 13-acetate, was enhanced at 72h.</p> |

| Reference: Yokota S et al. (2005, 096003) Species: Rat Gender: Male Strain: Sprague-Dawley (IGS) Weight: 303-472.2g Use: Rats were used after a 7-day acclimation period | DEP from Japan Particle Size: NR | Route: IT Instillation Dose/Concentration: Vehicle: 0.2 mL/animal DEP: 5 mg/animal Time to Analysis: Single exposure 0.5, 1, 2, 3, 6, 12, 24, 48h. | At 12 and 24 h post-instillation, circulatory neutrophil counts in the 5 mg DEP group were significantly elevated, and were 2.1-fold (12h) and 2.3 fold (24 h) in vehicle treated animals. 1 mg DEP caused an increase of approximately 0.4-fold in CNC at 6h. 12-O-tetradecanoylphorbol 13-acetate induced oxyradical production (ORP) in the isolated neutrophil was enhanced at 12 and 24 h after instillation with 5 mg DEP. In Serum, a marked elevation of CINC-1 and a slight elevation of MIP-2 were also observed, while TNF α was not detected. GM-CSF was not detected in serum 24 h post-instillation. |
| Reference: Yokota S et al. (2008, 190109) Species: Mouse Gender: Male Strain: ddy Age: NR Weight: 39.6-46.0g | DEP (DMSC (dichloromethane soluble-component), RPC (residual particle-component)) Particle Size: NR | Route: IT Instillation Dose/Concentration: 5mg/kg, 10mg/kg Time to Analysis: DMSC and RPC extracted from DEP. Mice acclimatized 7d. DEP, DMSC, or RPC instilled. BALF and blood obtained and G-CSF, GM-CSF, IL-6 measured 2, 4, 12, 24h postinstillation. | Inflammation: At 5mg/kg DEP increased the total cell and macrophage count. DEP or RPC increased neutrophils at 5 and 10mg/kg. 10mg/kg DEP or RPC increased macrophages at 4h and decreased at 12h. Hematology: Compared to 5mg/kg DEP, RPC increased RBC, WBC, and neutrophils. 10mg/kg RPC or DEP caused sustained increases in RBC, WBC, and neutrophils. Cytokines: 5mg/kg RPC markedly increased G-CSF and IL-6. Other cytokine increases at this dose were transient. 10mg/kg DEP increased IL-6 at 4h, and DEP or RPC increased G-CSF and IL-6 at 12h. DEP or RPC also increased IL-1 β . Myocardium: Myocardial MPO activity significantly increased in 5mg/kg RPC at 12 and 24h. Myocardial MIP-2 increased the most in 5mg/kg RPC, while LIX tended to be lowered by RPC. |

| Reference: Agopyan et al. (2003, 056065) Species: Human Tissues/Cell Types: BEAS-2B, NHBE, SAEC | PC: synthetic carboxylate-modified particles Particle Size: 2, 10 μm | Route: Cell Culture Dose/Concentration: PC2 = 0.83 g/mL or 3.4×10^9 particles/mL PC10 = 0.8 g/mL or 3×10^6 particles/mL Time to Analysis: PC2 = 12, 24, 8h PC10 = 2, 6, 12, 24h | Calcium Imaging: PC10 induced increase of Ca^{2+} concentration in all capsaicin-sensitive cells 100%. Similar reaction observed in cells exposed to PC2. However, more than 3-PC2s were required to induce a Ca increase unlike PC10. CPZ (10 μM) and amiloride could fully block PC-induced response. cAMP: Post 6h, a dose-dependent increase in cAMP was observed. Again, CPZ blocked increase by 70-90% depending on cell type: SAEC > NHBE ~ BEAS-2B. Apoptosis: PC10 and PC2 induced apoptosis time-dependently. PC2 was slower in induction than PC10. Post 48h, 80-95% cells were apoptotic in all cell types. Noncapsaicin-sensitive cells (which did not bind to particles) did not exhibit apoptosis. CPZ reduced apoptosis by 97% BEAS-2B, 96% NHBE and 98% SAEC. Amiloride did not block apoptosis. Necrosis: Induction of necrosis by PC2 and PC 10 was negligible. A slight increase from 1% to 2% was observed at 24-48h in NHBE and SAEC. BEAS-2B showed slight decrease from 3% to 4% in same time period. |
| Reference: Agopyan et al. (2004, 156198) Species: Human, Mouse Tissues/Cell Types: Human-NHBE, SAEC; Mouse-Wildtype and TRPV1(-/-) Terminal Ganglion Neurons (TG) ~ 257 Wildtype Neurons ~ 187 TRPV (-/-) Neurons | ROFA MSHA: Mt St Helen Ash Particle Size: NR | Route: Cell Culture Dose/Concentration: 100 $\mu\text{g/mL}$ ROFA or MSHA Time to Analysis: ROFA/MSHA in NHBE and SAEC = 2, 6, 24, 48 h ROFA/ MSHA in TG = 24 h cAMP measurements with NHBE and SAEC exposed to ROFA/MSHA = 6h | Calcium Imaging in NHBE and SAEC: In 100% of reactive cells, ROFA/MSHA induced an increase in Ca^{2+} . Levels remained elevated as long as PM bound to plasma membrane. Washing and disjoining PM from membrane caused Ca^{2+} to slowly decline to baseline. CPZ (or CPZ and amiloride) reversibly inhibited PM-induced rises in Ca^{2+} . Calcium Imaging in TRPV1(+/+) and (-/-) mice sensory neurons: All sensitive neurons in TRPV1(+/+) increased Ca^{2+} in response to ROFA. No effect of ROFA in TRPV1(-/-). cAMP: ROFA and MSHA induced increases in Ca^{2+} in NHBE and SAEC cells, which was completely blocked by cAMP. Apoptosis: ROFA or MSHA induced time-dependent apoptosis, peaking at 24 h. CPZ again inhibited this response. Neurons bound to PM (< 25 μm) induced apoptosis in TRPV1(+/+). Cells without bound PM or bound with PM (> 25 μm) showed no effect. No apoptosis occurred in the absence of Ca^{2+} . Necrosis: Necrosis for any of the cell types was negligible. PKA: Inhibition of PKA resulted in 90 + % apoptosis in NHBE and SAEC. Again, no apoptosis was observed in a Ca^{2+} free environment. |
| Reference: Ahn E-K et al. (2008, 156199) Species: Human Tissues/Cell Types: A549 | DEP: (6 cyl, 11L, turbo-charged, heavy-duty diesel engine, South Korea) Dex: anti-inflammatory (Sigma, St. Louis, MO) Particle Size: NR | Route: Cell Culture Dose/Concentrations: 0, 1, 5, 10, 50 and 100 $\mu\text{g/mL}$ of DEP Some cells pre-treated with 10, 20, 40, 50 $\mu\text{g/mL}$ of Dex. Time to Analysis: 24h | COX-2 Expression: Cells expressed dose-dependent increases in COX-2 expression after treatment with 10-100 $\mu\text{g/mL}$ of DEP. Treatment of 50 $\mu\text{g/mL}$ for 24 h induced statistically significant COX-2 expression in both mRNA and protein levels. Pre-treatment with Dex significantly reduced expression of COX-2 mRNA and protein. Dex treatment induced dose-dependent suppression of DEP-induced protein levels. PGE2 Levels: Levels of the inflammatory mediator, PGE2, increased when were cells exposed to 50 $\mu\text{g/mL}$ of DEP. Pre-treatment with 50 $\mu\text{g/mL}$ Dex completely inhibited DEP-induced release of PGE2. |

| Reference: Ahsan (2005, 156200) Species: Human Tissues/Cell Types: Trx-1-transfected Clone of Murine L-929 cells; Control Clone (L-929-Neo1); A549 | DEP: provided by Dr. Masaru Sagai, University of Health and Welfare, Aomori, Japan Particle Size: NR | Route: Cell Culture Dose/Concentration: DEP: 50 $\mu\text{g/mL}$ hTrx-1- or L-929-Neo1: 40 $\mu\text{g/mL}$ Pretreatment: rhTrx-1 (10 $\mu\text{g/mL}$) or DM-rhTrx-1 (NR) Time to Analysis: Pretreatment for 1 h. Parameters measured 3h post exposure. | ROS: DEP induced significant increases of ROS in L929-Neo1 cells. hTrx-1 cells showed no affect. RT-PCR revealed hTrx-1 mRNA expression in transfected cells but not control L929-Neo1 cells. Endogenous murine Trx-1 mRNA expression increased in control cells, but not in hTrx-1 cells. A549 cells had increased ROS levels but these levels were suppressed with rhTrx-1 pretreatment. Pre-treatment with DM-rhTrx-1 increased ROS levels more. Akt (antiapoptotic molecule): Phosphorylated Akt prevents apoptosis. DEP induced phosphorylation of Akt in control cells after 3h and dephosphorylation after 5h. In hTrx-1 cells, Akt remained phosphorylated after 5h. In A549 cells, Akt phosphorylated at 3h and slowly turned off at 12-24 h. Pre-treatment with rhTrx-1 blocked dephosphorylation. This suggests that Trx-1 preserves active form of Akt and thereby protects against cytotoxicity from DEP. |
| Reference: Alfaro-Moreno et al. (2002, 156204) Species: Human, Mouse, Rat Strain: Human-A549; Mouse-J7 74A.1, BALB-c Tissues/Cell Types: HUVEC, Mouse Fibroblasts, Rat Lung Fibroblasts (RLF) | PM ₁₀ : Collected from 3 zones in Mexico City: North (industrial), Center (business) and South (residential) Particle Size: PM ₁₀ | Route: Cell Culture 15000 cells/cm ² except: Cytotoxicity: Confluent Cultures 180,000 cells/cm ² . DNA Breakage: 20,000 cells/well. Cytokine Assays: 180,000 cells/cm ² Dose/Concentration: Cytotoxicity: 10, 20, 40, 80, 160 $\mu\text{g/cm}^2$ Apoptosis: 160 $\mu\text{g/cm}^2$ DNA Breakage: 2.5, 5, 10, 20, 40 $\mu\text{g/cm}^2$ Cytokine Assays: 10, 20, 40, 80 $\mu\text{g/cm}^2$ E-Selectin Expression: 40 $\mu\text{g/cm}^2$ Time to Analysis: Cytotoxicity: 24, 48, 72h; Apoptosis: 24 h; DNA Breakage: 72h; Cytokine Assays: 24 h | Cytotoxicity: Cytotoxic effect exhibited dose-dependency after 72h in proliferating cells of J774A.1, BALB-c and RLF cell lines. Proliferating Cells: Northern particles induced a statistically larger effect than central or southern particles. J774A.1 was more susceptible while BALB-c was less susceptible. A549 was most resistant to decreased viability during exposure. No significant variation in viability was observed when compared to the control. Particles were not cytotoxic among confluent cell growth for any cell lines when exposed to 20-160 $\mu\text{g/cm}^2$. Apoptosis: Overall, particles induced low rates of cell death via apoptosis. J774A.1 depicted similar levels of apoptosis when exposed to three PM zones, ~ 15% apoptotic cells measured. BALB-c was not reported. Results for the A549 measured apoptotic cells were: South- 4%, Central- 11% and North- 15%. HUVEC cells indicated an increase in apoptosis with northern particles. DNA Breakage: PM ₁₀ from all zones induced DNA breakage. A dose-dependent relationship was established with PM _{2.5} particles at concentrations of 10 $\mu\text{g/cm}^2$. The Southern zone required a higher dose of PM (10 $\mu\text{g/cm}^2$) to produce the same effect as other zones (2.5 $\mu\text{g/cm}^2$). Cytokines: Particles induced TNF- α and IL-6 secretion in J774A.1 cells dose-dependently. IL-6 increased significantly with central particles. PGE2 secretion in RLF cells induced by exposure to PM showed dose-dependent responses. PM from the central zone induced the most PGE2 secretion. Max secretion was observed at doses of 40 $\mu\text{g/cm}^2$ from all three PM zones. E-Selectin Expression: HUVEC cells showed a 25% increase in E-selectin expression after exposure to 40 $\mu\text{g/cm}^2$ of PM. |

| Reference: Amakawa et al. (2003, 156211) Species: Mouse, Human Strain: Mouse-ICR Tissues/Cell Types: AMs Gender: Mouse-Male; Human-Male Age: Mouse 6-7 wks; Human 20-24yrs | DEP (obtained from a 4JB1, Isuzu, 1500 rpm, 4cyl diesel engine) DEPE = DEP Extract (methanol) CB = Charcoal (Sigma) Particle Size: DEP: 0.4 μm , CB: 0.7 μm | Route: Cell Culture Mouse: 5×10^5 cells/mL Human: 3×10^5 cells/mL Dose/Concentration: DEP = 1 or 10 $\mu\text{g/mL}$; DEPE = 1 or 10 $\mu\text{g/mL}$; CB = 1, 10, 100 $\mu\text{g/mL}$ Time to Analysis: Human cells pre-treated with LPS 1 $\mu\text{g/mL}$. Murine cells pre-treated with SOD 300 IU/mL. Parameters measured 24h post exposure. | Cells: For mice, more than 90% of the cells were macrophages and over 90% were viable. For humans, 96% of the cells were macrophages, 3% lymphocytes and 1% neutrophils; over 95% of the human cells were viable. DEP Cytotoxicity: None observed Cytokines: DEP (10 $\mu\text{g/mL}$) suppressed release of TNF- α and IL-6 for both mice and humans in a dose-dependent manner. Murine cells pre-treated with LPS or IFN- γ released even less TNF- α and IL-6. IL-10 was unaffected. Human macrophages pre-treated with LPS also released lower levels of TNF- α , IL-6 and IL-8. ROS: Pre-treatment of SOD on murine cells partially attenuated the suppressive effect of DEP as well as decreased the production of ROS generated by DEP (10 $\mu\text{g/mL}$). Carbon: Carbon particles did not suppress TNF- α or IL-6 release from murine AMs; however, 100 $\mu\text{g/mL}$ of CB stimulated TNF- α production. Methanol: No cytotoxicity nor cytokine release effects were observed. DEPE: DEPE suppressed TNF- α and IL-6 release in a similar way as DEP. |
| Reference: Amara et al. (2007, 156212) Species: Human Cell Lines: A549, NCI-H292 | DEP = SRM 2975 CSC = cigarette smoke condensates (collected from Kentucky standard cigarettes, 2R4F; University of Kentucky) DC = DEP + CSC CB (Degussa, Frankfurt, Germany) Particle Size: CB: 95nm; DEP: NR | Route: Cell Culture Dose/Concentration: DEP = 5-10 $\mu\text{g/cm}^2$ CB = 10 $\mu\text{g/cm}^2$ CSC = 10 $\mu\text{g/cm}^2$ Time to Analysis: 6 or 24h | Inflammatory Markers: LDH of A549 was unaffected at either time point with DEP or CB. LDH increased with CSC at concentrations high than 10 $\mu\text{g/mL}$ at both time points. DC had no effect. Proteases: MMP-1 mRNA expression showed a dose dependent increase with DEP in A549 cells. DEP also increased MMP-1 in NCI-H292 cells. CB and CSC had no effect. MMP-1 mRNA expressions were inhibited by N-acetylcysteine antioxidant. Similar inhibition was observed with NOX4 oxidase. DC induced a similar effect to DEP. MMP-1 protein expression increased post 24 h with DEP. MMP-2, TIMP-1, TIMP-2 mRNA expression was unaffected. TGF: TGF- β mRNA expression was unaffected. ROS: DEP and DC increased ROS formation after 1h. DEP effect was inhibited by N-acetylcysteine antioxidant pre-treatment. MAP-Kinase: DEP induced MMP-1 expression increased ERK1/2 phosphorylation after 10 min, peaking at 30min, and returning to normal levels at 60min. Treatment with CBPs did not increase ERK1/2 phosphorylation whereas treatment with CSC resulted in phosphorylation. Only inhibitors of ERK1/2 reduced DEP induced MMP-1 activity. P38 and JNK inhibitors had no effect. |
| Reference: Anseth et al. (2005, 088646) Species: Human Cell Lines: A549; A549-p0 (lacking mitochondria) | s-ROFA: soluble portion Particle Size: 1.95 \pm 0.18 μm | Route: Cell Culture (3×10^5 cells/mL) Dose/Concentration: 100 $\mu\text{g/mL}$ Time to Analysis: Experiments conducted by spreading monolayer of Infasurf (calf lung surfactant extract on PBS, PBS + ROFA or conditioned media from A549 AEC. Parameters measured after 16h incubation period. | Lung Surfactant Gelation: ROFA alone and A549 conditioned media alone did not significantly alter Infasurf rheology. However, conditioned media from A549 AEC at 16h induced a significant increase in elastic storage and viscous loss moduli. Inhibiting ROS production lowered effect, indicating s-ROFA gelation mediated through ROS. ROS: ROS mediated through mitochondria as evidenced by the effect of ROFA-AEC on surfactant gelation in the presence of mitochondria ROS inhibitors as well as A549-p0 cells. |

| Reference: Auger et al. (2006, 156235) Species: Human Tissue/Cell Type: Nasal Epithelial Cells | DEP: SRM1650 PM _{2.5} : (obtained from a highway in Paris, France) Particle Size: DEP: 400 nm (mean diameter); PM _{2.5} | Route: Cell Culture (2-3.5x10 ⁴ cells/cm ²) Dose/Concentration: 10-80 µg/cm ² Time to Analysis: Cells treated on apical side. Parameters measured 24h following treatment. | Cytotoxicity (LDH): No cytotoxicity for DEP or PM _{2.5} (80 µg/cm ²). Cytokines: In non-stimulated ALI cultures, IL-8 was the most abundantly secreted cytokine, followed by GM-CSF, TNF-α, and IL-6 in decreasing levels of production. Amphiregulin was moderately, but consistently, secreted. After treatment, both DEP and PM _{2.5} induced IL-8 and amphiregulin release in a dose-dependent manner through the basolateral surface. PM _{2.5} stimulated IL-6 and GM-CSF release through the apical surface. ICAM-1 expression: No effect from DEP or PM _{2.5} . ROS: DEP and PM _{2.5} both increased ROS production in a dose-dependent manner. |
| Reference: Bachoual et al. (2007, 155667) Species: Mouse Cell Type: RAW 264.7 | PM ₁₀ from two Paris, France subway sites: RER and Metro CB (Frankfurt, Germany) TiO ₂ (Calais, France) DEP: SRM1650 (NIST) Particle Size: CB: 95nm; TiO ₂ : 150um; DEP: NR; RER PM ₁₀ : 79% < 0.5 µm, 20% 0.5-1 µm; Metro PM ₁₀ : 88% < 0.5 µm, 11% 0.5-1 µm. | Route: Cell Culture (40,000 cells/mL) Dose/Concentration: All particles: 0.01, 0.1, 1, 10 µg/cm ² Time to Analysis: 3, 8, 24h | Cell Viability: No effects from any particulate at concentrations up to 10 µg/cm ² for 24 h. Inflammatory Effect: Exposure of cells to 10µg/cm ² of RER or Metro induced time-dependent increase in TNF-α and MIP-2 protein release. This effect was similar to both locations. No effect was observed at low concentrations of PM ₁₀ . No effect of CB, TiO ₂ or DEP was observed. GM-CSF or KC production: RER and Metro PM ₁₀ did not induce any effect at any concentration. Effect on Protease mRNA Expression: Exposure of cells to 10 µg/cm ² RER or Metro PM ₁₀ did not modify mRNA expression of MMP-2 or -9 or their inhibitors TIMP-1 and -2. MMP-12 expression significantly increased after exposure to RER or Metro PM ₁₀ for 8h. Effects on HO-1 Protein Expression: Exposure to 10 µg/cm ² of RER or Metro PM ₁₀ for 24 h induced positive cytoplasmic staining for HO-1. |
| Reference: Batalha et al. (2002, 988109) Species: Rat Gender: Male Strain: SD Age: NR Weight: 200-250g | CAPs (Harvard Ambient Particle Concentrator) Particle Size: Mean: 2.7 µm | Route: Inhalation Chamber Dose/Concentration: Range: 73.5-733 µg/m ³ Time to Analysis: CAPs exposure 5h/d, 3d (consecutive). SO ₂ exposure to induce CB 5h/d, 5d/wk, 6wks. Killed 24h postexposure. | Histopathology: CAPs slightly increased the wall thickness of small pulmonary arteries and edema in the adventitia and hyperplasia of the terminal bronchiole and alveolar ducts epithelium. L/W ratio: The L/W ratio decreased in CAPs-exposed rats as particle mass, Si, Pb, SO ₄ ²⁻ , EC and OC increased. Univariate analyses showed significant negative correlations between the L/W ratio and Si and SO ₄ ²⁻ in normal rats and Si and OC in CB rats. Multivariate analysis showed only Si to be significant in both groups. |

| Reference: Becker et al. (2005, 088590) Species: Human Gender: Male and Female Age: 18-35yrs Cell Types: Alveolar Macrophages, NHBE | PM (Coarse, Fine, Ultrafine): (EPA, Chapel Hill, NC, Chem Vol Cascade) Particle Size: PM-C: PM _{2.5} ; PM-F: PM _{0.1} ; PM-UF: < 0.1 μm | Route: Cell Culture (0.5-1 x 10 ⁵ cells/well NHBE; 2-3 x 10 ⁵ /mL AM) Dose/Concentration: NH BE: 25, 50, 100, 250 μg/mL of PM; AMs: 50 μg/mL of DEP or 10ng/mL of LPS Time to Analysis: 18h for NHBE; overnight for AMs | Cytokines: All 3 fractions induced dose-dependent increases in IL-8 secretion with PM-c, PM-F, PM-UF (in order of decreasing effects). TLR-2 antibody blocked these particle induced IL-8 effects. Inhibitors of Endotoxin effects and TLR-4 activation: No effects were observed in NHBE, but all 3 fractions repressed the IL-6 release in AMs. TLR mRNA Expression: PM did not affect TLR-2 mRNA in NHBEs. PM-C and PM-F induced a slight increase in TLR-4 mRNA in NHBEs while PM-UF induced a substantial increase. PM-C increased TLR-2 mRNA in AMs and decreased TLR-4 mRNA in AMs. Induction of Hsp70: PM-C and PM-F induced Hsp70 in NHBE dose-dependently. Hsp70 was not induced in AM following particle stimulator. |
| Reference: Becker et al. (2005, 088592) Species: Human Gender: Male Age: 18-35yrs Cell Types: Alveolar Macrophages, NHBE | PM (Coarse, Fine, Ultrafine): (EPA, Chapel Hill, NC, Chem Vol Cascade) ROFA Fe, Si, Cr Components Oct 2001, Jan 2002, April 2002, July 2002 Particle Size: PM-C: 2.5-10 μm; PM-F: < 0.1 μm; PM-UF: < 0.1 μm | Route: Cell Culture (3-5 x 10 ⁵ cells/well NHBE; 2-3X10 ⁵ cells/mL AM) Dose/Concentration: NHBE: 11 μg/mL of PM; AM: 50 μg/mL of PM Time to Analysis: 18-24h NHBE; 18h AM | IL-8 Release in NHBE: PM-C and PM-UF induced effects. No effects from PM-F (all 4 dates). IL-6 Release in AM: All 3 fractions induced increase with later dates having generally lower effects. ROS (DCF): NHBE, at lower exposures, were observed to be more responsive to PM than AMs. AM exhibited highly variable results over time. ROS (DHR): NHBE cells were observed to be more responsive to PM than AMs. AM responsiveness to PM increased over 4 time periods; this was not observed in NHBE. Seasonal Variability: Coarse particles were more potent than F and UF regardless of the month, and the potency for PM to induce IL-6/IL-8 production varied significantly. Coarse particles induced a 5-25 fold change in IL-6 release for AMs and a 3-6 fold change in IL-8 release for NHBEs. Metal Correlation to IL-6/8 induction: Fe and Si were positively associated with IL-6 release in AMs incubated with the coarse fraction. Cr was positively associated with IL-8 release in NHBE cells incubated with F or UF. |
| Reference: Beck-Speier et al. (2005, 156262) Species: Human, Canine (Beagle) Cell Types: Human AMs, Canine AM (CAM) | DEP = SRM 1850a (NIST) EC = Ultrafine Elemental Carbon (spark discharge) P90 = Printex 90 (Carbon Black, Degussa) PG = Printex G (Carbon Black, Degussa) Particle Size: (in diameter) DEP: 20-40nm; EC: 5-10nm; P90: 14nm; PG: 51nm | Route: Cell Culture (1X10 ⁶ cells/mL AM) Dose/Concentration: All particles: 1 (EC only), 3.2, 10, 32, 100 μg/mL Time to Analysis: 60min | Phagocytosis: All particles were phagocytosed by CAM within 60 min. Oxidative Potential: EC showed a very high effect. DEP, P90 and PG had no effect Formation of Lipid Mediators: DEP, EC P90 and PG increased arachidonic acid and PGE ₂ /TXB ₂ in CAM in a dose-dependent manner. Only EC increased LTB ₄ and 8-isoprostane. ROS Activation: All particles increased activity in canine macrophages with EC, P90 and PG increasing activity in a dose-dependent manner. DEP increased activity in canine macrophages. Similar results were observed human alveolar macrophages but only EC and P90 were tested. Particle Mass vs Particle Surface Area: PGE ₂ /TXB ₂ effects were highly correlated with particle surface area. |

| Reference: Bitterle et al. (2006, 156276) Species: Human Cell Type: A549 | C-UFP = ultrafine carbonaceous particles (obtained from a spark discharge aerosol generator GFG 1000, Palas, Karlsruhe, Germany) Particle Size: 90nm (count median mobility diameter) | Route: Cell Culture (3 x 10 ⁷ cells) Dose/Concentration: 44 ± 4 ng/cm ² ; 87 ± 23 ng/cm ² ; 230 ± 70 ng/cm ² (ng/cm ² = total mass of deposited particles per cm ² cell monolayer after 6h exposure) Time to Analysis: 6h | Cell Viability: Exposure to clean air resulted in a 93.7 ± 9.1% viability. Exposure to low, mid nad high doses of C-UFP resulted in a 94.9 ± 9.5% viability. Thus C-UFP had no effect on cell viability. Interleukins: Clean air controls induced a 2-3 fold increase in IL-6 and IL-8 production vs submersed control. U-CFP exposures induced a similar effect on IL-8 and IL-6 levels. Antioxidant enzyme HO-1: The mid dose increased transcription of HO-1 by 2.7 fold. There was no observed effect at the high dose level which indicates possible cytotoxicity. |
| Reference: Blanchet et al. (2004, 087982) Species: Human Cell Type: 16HBE | PM _{2.5} (Vitry-sur-Seine, Paris, France) DEP = SRM 1650a CB = Carbon Black (Degussa) TiO ₂ (Huntsman) Particle Size: CB: 95 nm; TiO ₂ : 150 nm | Route: Cell Culture (45,000 cells/cm ²) Dose/Concentration: All particles: 0.1, 1, 10, 30 µg/cm ² Time to Analysis: 6, 18, 24, 30h | Amphiregulin Expression: DEP and PM _{2.5} both increased AR mRNA expression from 6 to 30h, with PM _{2.5} inducing higher expression levels than DEP. Both DEP and PM _{2.5} increased AR protein secretion. No observed effect for CB and TiO ₂ . PM _{2.5} induced protein secretion dose-dependently. Signal Pathways in AR Secretion: MAP kinase and tyrosine kinase inhibitors reduced effects of DEP and PM _{2.5} but p38MAP kinase inhibitor did not. Role of Oxidative Stress: N-Acetylcysteine blocked AR secretion following PM _{2.5} . Antioxidant enzyme catalase had no effect. Cytokines: DEP induced a significantly high release of GM-CSF, higher than PM _{2.5} . EGFR antibody reduced GM-CSF release at 0.25 µg/mL dose. |
| Reference: Bonvallot et al. (2001, 156283), 2001 #7852} Species: Human Cell Type: 16HBE14o- | DEP: SRM 1650 OE-DEP: dichloromethane extract (2x) of DEP nDEP: native DEP sDEP: nDEP - OE-DEP CB: Carbon Black FR103 (Degussa) BaP: Benzo[a]pyrene CB: 95nm NR Particle Size: CB: 95nm; DEP: NR | Route: Cell Culture (3 x 10 ⁶ cells) Dose/Concentration: DEP, sDEP, nDEP and CB = 10 µg/cm ² OE-DEP = 15 µg/mL BaP = 0.25, 50 and 250 µg/mL Time to Analysis: 24h | Proinflammatory Response: At 10µg/cm ² , nDEP induced GM-CSF release by 4.7 fold. OE-DEP increased GM-CSF by 3.7 fold. BaP and sDEP also induced increases of CN-CSF but had smaller effect. CB had no effect. NF-κB Activation: nDEP and OE-DEP induced enhanced degradation of IκB at 2-4h and 1h respectively. NF-κB DNA binding was enhanced by OE-DEP (15 µg/mL, peak < 1h) and nDEP (10 µg/cm ² , peak at 2-h with plateau till 4 h). Both OE- and nDEP enhanced NF-κB DNA binding levels were higher than BaP enhanced binding levels. CYP1A1 mRNA: The CYP1A1 mRNA level was markedly increased in nDEP and OE-DEP treated cells in comparison with their respective controls. Radical Scavengers (decreased ROS in situ): Increases of GM-CSF and NF-κB DNA binding by nDEP and OE-DEP was attenuated by radical scavengers. MAPK Activation: Increases by nDEP and OE-DEP of GM-CSF was inhibited by Erk1/2 inhibitor but not by p38 inhibitors. Both nDEP and OE-DEP triggered Erk1/2 and p38 phosphorylation. sDEP affected p38 phosphorylation only. |
| Reference: Brown et al. (2007, 156300) Species: Human, Mouse Cell Type: PBMC, A549 (Human); J774A.1 (Mouse) | PM ₁₀ (London, England) CM from PM ₁₀ -treated human monocytes Particle Size: PM ₁₀ | Route: Cell Culture (1 x 10 ⁶ cells/mL J774A.1; 5X10 ⁵ cells/mL PBMC; 5X10 ⁵ cells/well A549) Dose/Concentration: PM ₁₀ : 75 µl (10 µg/mL); CM: 250 µl; tBHP: 12.5 µm (in J774); TNF: 0, 500pg, 1ng, 10ng Time to Analysis: tBHP: 1, 2, 4h; PM: 4h; TNF: 18h | Cytokines: PM ₁₀ induced release TNF-α protein from PBMCs at 10µg/mL for 4h. Further inhibited by verapamil and BAPTA-AM. Calmodulin inhibitor W-7 had no effect. CM increased IL-8 from A549 cells 3 fold. Verapamil, BAPTA-AM and W-7 significantly inhibited IL-8 release induced by CM. ICAM-1: A549 cells treated with TNF-α showed dose-dependently effect of TNF-α on ICAM-1 upregulation at 18h. CM also induced upregulation. Verapamil, BAPTA-AM and W-7 fully inhibited CM-induced upregulation. |

| Reference: Calcabrini et al. (2004, 096865) Species: Human Cell Type: A549 | PM _{2.5} (Rome, Italy) Particle Size: PM _{2.5} | Route: Cell Culture (5 x 10 ⁴ cells/well) Dose/Concentration: 30, 60 µg/cm ² (aliquot of 0.1 µg/ul) Time to Analysis: 5, 24, 48, 72h | Particle Characterization: Components measured include C-rich particles, Ca sulfates, silica, silicates, Fe-rich particles, metals. Carbonaceous particles made up majority of PM. Cell Surface Changes: PM deposited on the cell surface showed dose and time-dependent increases in microvilli rearrangement and cell shape alterations without affecting apoptotic markers for up to 72 h. PM internalization: At 24 h with the low dose, aggregates of PM in cytoplasm or surrounded by membrane was observed. With the high dose, large particle aggregates often close to nuclear envelopes were observed. Cytoskeleton: At 72h PM induced dose-dependent alterations from rearrangement/interweaving of microtubules to bundling of microtubules with some shortening/disruption. Cell Growth: PM decreased cell growth in a dose and time –dependently manner ROS: PM increased ROS at the high dose for 5h but not at 24 h or with the low low dose. Cytokines: PM induced TNF-α peaked at 5h at high dose and 48h at low dose, both ND at 72h. PM induced IL-6 starting at 24 h thru 72h in time and dose dependent manner. |
| Reference: Cao et al. (2007, 156322) Species: Human Cell Type: HAEC | NIST-DEP: collected using a diesel forklift and hot bag filter system. (NIST, Minneapolis, MN) C-DEP: obtained from a 30-kw (40 hp) four-cylinder Deutz BF4M1008 diesel engine (U.S. EPA) Organic extract fraction of particles NIST- DEP 2% C-DEP 20 % Particle Size: NR | Route: Cell Culture (5 x 10 ⁵ cells) Dose/Concentration: NIST-DEP, C-DEP: 0, 12.5, 25, 50, 100, 200 µg/mL Time to Analysis: 1-4h | Cell Viability: DEP had no effect. Stat3: Both DEPs induced time-dependent phosphorylation of Stat3 in cytoplasm. NIST-DEP induced phosphorylation dose-dependently from 12.5 to 50 µg/mL but stayed level at 100 and 200 µg/mL. p-Stat3 induction was inhibited by antioxidant BHA though it was reactivated with exposure to H2O2. Reaction induced by H2O2 was similar to that of DEP. pStat3 Nuclear Transport: NIST-DEP induced cytoplasmic pStat3 to move from cytoplasm into nucleus. pEGFR Dephosphorylation: After 4h of NIST-DEP exposure, dephosphorylation was inhibited for up to 90 min. |
| Reference: Chang C-C et al. (2005, 097776) Species: Human Cell Type: A540, THP-1 | UfCB (Printex 90, Degussa) Particle Size: 14nm diameter | Route: Cell Culture (7 x 10 ⁶ cells) Dose/Concentration: 100 µg/mL Time to Analysis: 4h | ROS in THP-1 and A549: UFCB increased ROS. NAC pretreatment blocked most of the UFCB-induced ROS production. VEGF in THP-1: UFCB increased VEG. NAC decreased the UFCB effects below those of the control. VEGF in A549: Produced similar, but less marked, results as with THP-1. |
| Reference: Chauhan et al. (2004, 096882) Species: Mouse Strain: BALB/c Cell Type: RAW 264.7 (leukemia virus transformed macrophages); J774A.1 (from a tumor); WR19M.1 (leukemia virus transformed macrophages) | EHC-T: total EHC-93 (Env Health Ctr, Ottawa, Canada) EHC-I: insoluble EHC EHC-S: soluble EHC SRM1648: urban particulate St.Louis (NIST) SRM1649: urban dust/organics Washington (NIST) VERP: fine PM _{2.5} (Vermillion, Ohio) Cristobalite: SRM 1879 (NIST) TiO ₂ : SRM 154b (NIST) Particle Size: EHC-93: 0.5 µm (median diameter); Cristobalite, SRM 1648, SRM 1649, TiO ₂ : NR; VERP: PM _{2.5} | Route: Cell Culture (15000 cells/well) Dose/Concentration: Particle suspensions: 20, 50, 100 µg/well LPS: 0-5 µg/mL IFN-γ: 0-1000 U/mL Time to Analysis: Particles added to culture at 0h, LPS and IFN-γ added at 2h. Parameters measured after 22h incubation period. | Stimulation with LPS/IFN-γ: LPS and IFN-γ each induced NO release. Combination of LPS and IFN-γ produced larger effect in all cell lines. L-NMMA, NOS inhibitor, suppressed most of the NO production with 100nmol/L. Cellular Viability and Cytotoxicity: Exposure of cells to particulates did not result in overt cytotoxicity or excessive loss of cellular material. There was no correlation between the cytotoxicity of the particles in the surviving cells and the loss of protein mass in monolayers. Nitrite Production: EHC-T, EH-93-I, SRM1648 and SRM 1649 produced dose-dependent decreases. Cristobalite only decreased at higher doses. No effect from EHC-S, VERP or TiO ₂ . iNOS: EHC-I, EHC-T, Crisobalite and SRM1648 inhibited iNOS expression. TiO ₂ had no effect. EHC sol, SRM 1649 and VERP were not tested. |

| Reference: Chauhan et al. (2005, 155722) Species: Human Cell Type: A549 | EHC-T: total EHC-93 EHC-I: insoluble EHC EHC-S: soluble EHC Cristobalite (SiO ₂): SRM-1879 TiO ₂ : SRM-154b Particle Size: EHC-93: 0.4 μ m (median physical diameter); TiO ₂ , SiO ₂ : 0.3-0.6 μ m | Route: Cell Culture (150000 cells/flask) Dose/Concentration: All particles: 0, 1, 4, 8 mg/5ml Time to Analysis: 24h | Cellular Viability: Decreased after exposure to EHC-T, EHC-I and cristobalite. Rate of reduction was not consistent across doses. EHC-S and TiO ₂ had no effect on viability. ET-1: Release of ET-1 peptide decreased dose-dependently for EHC-T, -S and -I. Fractions of EHC-S and EHC-I were more potent than EHC-T. TiO ₂ and Cristobalite also reduced ET-1 secretion although this was not consistent across the dose range. Cytokines: Results showed no detectable amounts of GM-CSF, IL-1 β or TNF- α in cell culture supernatants. IL-8 increased dose-dependently with EHC-T, EHC-I and cristobalite. VEGF: VEGF significantly increased dose-dependently with EHC-T, EHC-S and cristobalite. EHC-S induced a significant decrease in VEGF. Gene Expression: mRNA levels for preproET-1 reduced at 24 h for all particle types. EHC-S induced a significant decrease in ET-1 expression at this high dose. ECE-1 mRNA expression increased with EHC-T and EHC-I. Other particles had no effect. ETaR mRNA increased with EHC-T, EHC-S, and TiO ₂ in biphasic manner where the highest expression of mRNA was seen at the middle dose levels. EHC-S had no effect. ETbR mRNA increased with a low dose of EHC-T and decreased with a high dose of EHC-T. EHC-S, EHC-I and cristobalite induced an increase of ETbR. TiO ₂ induced a significant decrease. Proteases: mRNA levels for MMP-2 reacted similarly to preproET-1. mRNA levels for TIMP-2 was significantly induced with EHC-I. EHC-T and EHC-S induced small effects. |
| Reference: Cheng et al. (2003, 156337) Species: Human Cell Type: A549 | DEP-h: DEP with high sulfur DEP-LS: DEP with low sulfur GEP: gasoline engine exhaust particles Primed cells pretreated with TNF- α Particle Size: DEP-h: 15.9nm; DEP-LS: 17.7nm; GEP: 8.3nm | Route: In Vitro Cellular Exposure (Exhaust flow-through cell culture with air-cell-interface, exhaust diluted 10-15x with 8x10 ⁵ cells/mL) Dose/Concentration: DEP (total): 1.5-3.5x10 ⁶ particles/cm ³ air; GEP (total): 1-2x10 ⁶ particles/cm ³ air; TNF- γ : 5ml (25 ng/ml) Time to Analysis: 60-360 min | IL-8: DEP-h induced a 3 fold increase in IL-8 than that of the control. DEP-LS also induced increases. Primed cell cases had higher levels (10x) than unprimed when exposed to DEP-LS. DEP-h induced higher levels of IL-8 than DEP-LS. This response lasted for up to 6h. GEP induced a statistically insignificant increase of IL-8 in unprimed cells. With primed cells, GEP induced levels of IL-8 that exceeded those of DEP-h and DEP-LS. This response lasted for 1-2 h. |
| Reference: Chin et al. 2002 Species: Rat, Human Cell Line/Type: RAW 264.7 (Rat), MHS Alveolar Macrophage Cell Line (Rat), A549 (Human) | CB: (N339, with benzo[a]pyrene absorbed on surface. | Reference: Churg A et al. (2005, 088281) Species: Rat Strain: Sprague-Dawley Weight: 250g Cell Type: Epithelial Cells of Tracheal Explants | EHC93 (Ottawa Urban Air Particles) TiFe = Iron-loaded fine TiO ₂ (obtained from Aldrich Chemicals, Milwaukee, WI) 3-4um EHC93 0.12 ± 1.4 µm TiO ₂ Particle Size: EHC-93: 3-4 µm (MMAD); TiFe: 0.12 ± 1.4 µm (geometric mean diameter) | Route: Cell Culture Dose/Concentration: EHC-93, TiFe: 500 µg/cm ² Time to Analysis: 1, 24h. Some experiments (referred to as 2h) explants transferred to different dish and incubated for additional hour. Pre-treated with Inhibitors/Chelators for 2h. | Activation of NF-κB: Both particle types increased nuclear translocation of NF-κB. TiFe and EHC-93 increased NF-κB 1.5 fold at 1h. TiFe increased NF-κB 3.5 fold at 2h. EHC-93 increased NF-κB more than 2 fold. TiO ₂ by itself did not increase NF-κB at any exposure duration. Activation of NF-κB into tracheal epithelial cells: No evidence of dust particles was observed (EHC-93 or TiO ₂) in the epithelial cell cytoplasm at 2h. No evidence of morphologic cell damage from particles was observed. Colchicine: Treatment with colchicine did not prevent NF-κB activation. Inhibitors/Activators: Tetramethylthiourea (TMTU) (membrane-permeable active oxygen scavenger), Deferoxamine (redox-inactive metal chelator), PPS (Src inhibitor) AG1478 (epidermal growth factor receptor inhibitor) prevented NF-κB activation in both EHC93 and TiFe exposed-cells. Iron-containing citrate extract of both dusts increased NF-κB activation in both EHC93 and TiFe exposed-cells. |
| Reference: Courtois et al. (2008, 156369) Species: Rat Strain: Wistar Cell Line: Dissected intrapulmonary arteries from rats used in corresponding in vivo experiments | PM (SRM 1648) (63% inorganic carbon, 4-7% organic carbon, mass fraction > 1%: Si, S, Al, Fe, K, Na) UF carbon black (FW2, P60) Particle Size: SRM 1648 mean diameter 0.4 µm; ultrafine carbon black: FW2- 13nm, P60- 21nm | Route: Cell Culture Dose/Concentration: 100, 200 µg/mL Time to Analysis: 24h incubation | NO: Generally, Ach-induced relaxation in intrapulmonary arteries decreased, Ach-induced cGMP accumulation decreased, and relaxation by SNP or DEA-NO also decreased. UF carbon black did not affect NO responsiveness. Oxidative Stress, Inflammatory: Dexamethasone prevented SRM 1648-induced impairment of the Ach relaxation response but antioxidants did not. TNF-α, MIP2, IL-8 increased. ROS was not affected. |
| Reference: Dagher et al., (2007, 097566) Species: Human Cell Type: L132 (Normal Lung Epithelial Cells) | LC10, LC50 = PM _{2.5} (collected Jan-Sept in Dunkerque, France) Particle Size: cumulative frequency: 0.5 µm: 34%; 1 µm: 64%; 1.5 µm: 79%; 2 µm: 87%; 2.5 µm: 92%; 5 µm: 98%; 10 µm: 100% | Route: Cell Culture (3 x 10 ⁶ , 1.5 x 10 ⁶ , 0.75 x 10 ⁶ cells/20mL) Dose/Concentration: LC10: 19 µg/mL; LC50: 75 µg/mL Time to Analysis: 24, 48 or 72h | p65 Protein: Phosphorylation of p65 increased in PM-exposed L132 cells in dose-dependent manner. IκBα Protein: Phosphorylated IκBα protein concentrations increased in cytoplasm with both particle types at all time points. p65 and p50 DNA: p65 DNA binding increased at 24h with LC10 and LC50, at 48h with LC10, and at 72h with LC10 and LC50. p50 DNA binding increased at all time points with LC10 and LC50. |
| Reference: Dai et al. (2003, 087944) Species: Rat Strain: Sprague-Dawley Weight: 250g Cell Type: Tracheal Explants | EHC-93 (Environmental Health Center, Ottawa) DEP: SRM 1650a (NIST) Particle Size: EHC-93: 3-4 µm (MMAD); DEP 1.55 ± 0.04 µm (CMD) | Route: Cell Culture Dose/Concentration: ECH, DEP: 500 µg/cm ² Time to Analysis: Exposed for 1h. Parameters measured following a 7d incubation period. | Hydroxyproline: EHC93 induced an almost 3 fold increase in explant hydroxyproline. DEP increased tissue hydroxyproline 2.5 fold. Procollagen: EHC-93 doubled gene expression of procollagen. Procollagen gene expression could be fully inhibited by SN50, TMTU or treatment of the PM with DFX. Treatment of explants with p38 or ERK (inhibitors) had no effect on procollagen expression. DEP induced an increase in procollagen gene expression but this increase was completely prevented by SN50 and MAP kinase inhibitors (SB203580 and PD98059). Neither TMTU or DFX has any effect. TGFβ1: Treatment of explant with EHC93 approximately doubled gene expression for TGFβ1. Treatment with SN50, TMTU and fetuin (TGFβ antagonist) blocked increase. DFX, MAP kinase inhibitors (SB203580 and PD98059) had no effect. DEP roughly doubled TGFβ1 expression. SN50 and MAP kinase inhibitors (SB203580 and PD98059) fully blocked this effect. TMTU and DFX had no effect. |

| Reference: Doherty SP et al. (2007, 096532) Species: Rat Strain: NR8383 Cell Types: AMs | Ratios of: V: Fe; Al: Fe; Mn: Fe V = sodium vanadate (NaVO ₃) Al = aluminum chloride hexahydrate (AlCl ₃) Mn = manganese chloride tetrahydrate (MnCl ₂) Fe = ferric chloride hexahydrate (FeCl ₃) Ratios based on PM _{2.5} measurements from NYC, LA and Seattle Particle Size: Metals from PM _{2.5} samples | Route: Cell Culture (2X10 ⁵ cells/mL) Dose/Concentration: Fe = 16 μ mol (equivalent to urban NYC 500 μ g PM _{2.5}); V and Mn tested in molar ratios of 0.02 to 0.4 relative to Fe; Al tested in molar ratios of 0.125 to 8 relative to Fe. Time to Analysis: 20h | IRP: Addition of V increased IRP activity 5 to 9 fold. Though there was no seeming dose responsivity, IRP activity remained strongly elevated over the range of V:Fe ratios tested. Addition of Mn only resulted in an effect at 0.1 molar ratio (two-fold), not at higher or lower ratios. Al resulted in peak increases of 5 fold at molar ratios 2 while declining to 2 fold at molar ratios 4 and 8. Cytotoxicity: Al was cytotoxic at molar ratios of 4 and 8. All other Al, V, Mn ratios had no effect. Mixtures: The combination of metals tested at NYC PM ratios and V drove all the Fe transport activity. Combinations of V+Mn and V+Al increased activity more than V:Fe alone. |
| Reference: Doornaert, et al. (2003, 156410) Species: Human Cell Line/Type: 16HBE14o-; P-HBE | DEP: SRM 1650 (NIST) CB: (Sigma, France) DPC: Dipalmitoyl phosphatidylcholine (positive control) 0.5 μ m Particle Size: NR | Route: Cell Culture (10 ⁵ -2x10 ⁶) Dose/Concentration: DEP and CB: 1- 100 μ g/mL Time to Analysis: Parameters measured 24, 48, 72h post exposure. 1-HBE Cell Deadhesion Capacity: 24h, evaluation of detachment performed every 5min for 40min after. Cell Wound Repair Capacity: 24 h, repair evaluated 3.5, 7, 24 h after. | Cytotoxicity: DEP was cytotoxic at 100 μ g/mL at all time points in a time-dependent manner. CB and DPC cytotoxicity was substantially lower but significant at 72h. Phagocytosis: 1-HBE cell levels that were in contact with DEP or CB or have phagocytized those particles increased in a dose-dependent manner. DEP induced greater levels of cell contact and phagocytosis than CB. F-actin: Only DEPs were engulfed by F-actin stained cell fragments. Actin CSK Stiffness: DEP (5, 20, 100 μ g/mL) induced net dose-dependent decrease in cytoskeleton stiffness and a dose-dependent decrease in actin cytoskeleton stiffness. CB produced no significant decrease. Adhesion Molecules: DEP induced a concomitant reduction of both CD49 (α 3) and CD29 (β 1) integrin subunits and a decrease in level of CD44 (HBE cell-cell and cell-matrix adhesion molecule) at both 20 and 100 μ g/mL. Proteases: DEP also induced an isolated decrease in MMP-1 expression without change in tissue inhibitor of TIMP-1 or TIMP-2 at 100 μ g/mL. CB produced no change or insignificant results. 1-HBE Cell Deadhesion Capacity: DEP exposure induced a dose-dependent amplification of cell detachment at 5min of incubation and onward. Cell Wound Repair Capacity: DEP inhibited wound repair/wound closure in a dose-dependent manner. |
| Reference: Dostert et al. (2008, 155753) Species: Human Cell Line/Type: THP1, monocyte-derived macrophages (MM) | Asbestos Silica DEP CSE: cigarette smoke extract MSU: monosodium urate crystals Particle Size: NR | Route: Cell Culture Dose/Concentration: Asbestos: 0.1, 0.2 mg/mL; Silica: 0.1, 0.2, 0.25, 0.5 mg/mL; DEP: 0.2, 0.25, 0.5 mg/mL; CSE: 5%, 10% in solution mg/mL; MSU: 0.1, 0.2 mg/mL Time to Analysis: 1, 3, 6h | IL-1β: Increased levels of IL-1 β with asbestos and silica were observed in THP1 at 6h. CSE and DEP had no effect. MM also had increased levels with asbestos, silica and MSU at high dose levels only. Caspase-1: Asbestos increased caspase-1 activity. ROS: Asbestos doses in THP1 exhibited an increase in ROS formation. |
| Reference: Doyle, et al. (2004, 088404) Species: Human Cell Type: A549 from non-smoking adults | BD: 1,3-butadiene, known carcinogen Acrolein: photochemical and NO product of BD in atmosphere Acetaldehyde: photochemical and NO product of BD in atmosphere Formaldehyde: photochemical and NO product of BD and ISO in atmosphere ISO: isoprene, 2-methyl analog of BD Methacrolein: photochemical and NO product of ISO in atmosphere Methyl vinyl ketone: photochemical and NO product of ISO in atmosphere Particle Size: NR | Route: Environmental Irradiation (smog) Chambers Dose/Concentration: 50 ppb NO; 200 ppbV ISO, BD Time to Analysis: Exposed to gases for 5h. Analysis 9h post exposure. | Cytotoxicity: ISO+NO and BD+NO induced small increases of LDH in A549. However, ISO+NO+light and BD+NO+light increased LDH levels 4-6 fold indicating photochemical products of ISO and BD are highly cytotoxic. LDH levels of each combination were equivocal. IL-8 Protein: Methacrolein, methyl vinyl ketone and formaldehyde (products of ISO) increased IL-8 protein levels significantly. ISO+NO had no effect. BD photochemical products (acrolein, acetaldehyde and formaldehyde) also increased IL-8 protein, more than doubling the photochemical products induced by ISO. BD+NO had no effect. IL-8 mRNA: IL-8 mRNA expression also increased with photochemical products of ISO and BD but did not reach a statistically significant level. |

| Reference: Duvall, R.M. (2008, 097969) Norris, G.A. Dailey, L.A. 2008 Species: Human Cell Type: Airway Epithelial Cells | PM-F, -C, -UF Particles collected from: Seattle, WA (PM-S); Salt Lake City, UT (PM-SL); Phoenix, AZ (PM-P); South Bronx, NY (PM-SB); Hunter College, NY (PM-HRterling Forest, NY (PM-SF) Particle Size: Coarse: > 2.5 μm ; Fine: < 2.5 μm ; Ultrafine: < 0.1 μm | Route: Cell Culture (100,000 cells/cm ²) Dose/Concentration: 5 mg/ml Time to Analysis: 1, 24h post exposure | Particle Characterization: PM-HR, PM-SL and PM-S contained the highest UF, F, and C concentrations. PM-SB and PM-HR had similar F and C concentrations. Sulfate was highest in PM-F for all sites except in PM-SB and PM-HR. Wood combustion was highest in PM-SL, PM-S, PM-P. Soil dust was highest in PM-SL and PM-S. IL-8: PM-UF induced a greater increase in IL-8 than other types of PM except PM-P. PM-UF is associated with vanadium, lead, copper, sulfate. PM-F-HR caused the greatest increase followed by PM-SB. PM-F-SF and PM-F-P was least effective. PM-C also caused an increase in IL-8 levels and was associated with vanadium and elemental carbon. COX-2: PM-F-S induced the greatest increase in COX-2 expression. Other PM-F sites induced similar increases. UF PM had no effect. PM-C, associated with elemental carbon, induced increases. HO-1: PM-F-SF induced the greatest increase in HO-1. PM-F-SL was the least effective. UF PM had no effect. PM-C, associated with copper, barium and elemental carbon, caused an increase. |
| Reference: Dybdahl M et al. (2004, 089013) Species: Human Cell Type: A549 | DEP: SRM 1650 (NIST) Particle Size: 90nm (MMAD) | Route: Cell Culture (10 ⁵ cells/mL) Dose/Concentration: 0, 10, 50, 100, 500 $\mu\text{g/mL}$ Time to Analysis: 2, 5, or 24h | Cytokines: DEP induced dose-dependent increases of IL-1 α , IL-6, IL-8 and TNF- α at 24 h. Cytokines increased between 4 and 18 fold at the highest DEP dose as compared to controlled cells. DEP also increased IL-6 mRNA expression levels in a dose and time-dependent manner. IL-6 mRNA levels increased 14 fold at 24 hours, 8 fold at 5 hours, and 2 fold at 2 hours. Cell Viability: DEP exposure did not decrease cell viability at any dose tested. |
| Reference: Dybdahl M et al. (2004, 089013) Species: Mouse Strain: BALB/CJ Gender: Female Age: 10wks Weight: ~ 20g | DEP: SRM 1650 (NIST) Particle Size: 90nm (MMAD) | Route: Nose-only Inhalation Dose/Concentration: Single exposure: 20 or 80 mg/m ³ ; 4 exposures: 5 or 20 mg/ m ³ Time to Analysis: Single 90min or four 90min exposures. | Inflammation: DEP induced a dose- and time-dependent expression of pro-inflammatory cytokines. A single high dose of DEP induced an increase in IL-6 mRNA levels persisting for at least 22 hours. However, at the same cumulative dose given as 4 doses, the IL-6 level was only increased 1 hour after exposure. Cytokines: Only IL-6 was induced after DEP exposure. A single 90 minute inhalation (at 20 mg/m ³) increase IL-6 gene levels dose-dependently in the lung and was significantly higher than control levels at both 1 and 22 hours post exposure. Repeated exposures at 5 mg/m ³ did not affect IL-6 levels. BAL Cells: Inhalation of DEP did not decrease viability of BAL cells. 1 hour after the last dose, mice exposed to 20 mg/m ³ exhibited a 3 fold increase in total cell numbers as compared to control. The number of total cells and neutrophils in BAL fluid were still increased 22 hours after exposure to 20 mg/m ³ DEP. BAL cell population was not affected by repeated exposures to 5 mg/m ³ DEP. Lymphocyte numbers were also unchanged by DEP. |

| Reference: Fritsch, S.Diabate, S. (2006, 156452) Species: Mouse Cell Type: RAW 264.7 | MAF02: incinerator fly ash (collected by electrostatic precipitation in commercial municipal waste incinerator facility) composition representing 12% of total mass (mg/g): Fe (9.1); Pb (23.3); Zn (75.7); C (7.5) Particle Size: 165nm (modal value) | Route: Cell Culture (1 x 10 ⁶ cells/well) Dose/Concentration: 6.3-188 µg/cm ² for Toxicity; 2.6, 6.5, 13.2 µg/cm ² for Arachidonic Acid; 13.2 µg/cm ² for MAPK Pathway; Other doses noted in Effect of Particles Time to Analysis: 1, 2.5, 5, 24 h | Toxicity: Viability decreased from 99% to 18% at 62.5-188 µg/cm ² . Lower doses had no effect. Arachidonic Acid: At 2.5h, AA level increased 2 fold for 6.5 µg/cm ² and 6 fold for 13.2 µg/cm ² . No increase was observed after 5h. MAPKs: Cells pretreated with PD98059, an inhibitor of MEK-1, inhibited AA liberation due to MAF02 treatment of 13.2 µg/cm ² COX-2: A time-dependent increase of COX-2 protein expression was exhibited at 2.5 and 5h. ROS: A dose-dependent increase in ROS formation was observed at concentrations greater than 31.3 µg/cm ² after 3 hours. GSH: There was an observed increase of production at 20h. Doses greater than 60 µg/cm ² reduced total glutathione. HO-1: There was an observed dose-dependent increase in expression at 4 hours. |
| Reference: Fujii et al. (2002, 036478) Species: Human Cell Type: HBEC (from current smokers), AMs, Co-Culture: AMs + HBEC Age: HBEC: 48-70yrs | PM ₁₀ : EHC-93 (Ottawa, Canada) Particle Size: PM ₁₀ | Route: Cell Culture (HBEC: 2.5-3 x 10 ⁶ cells/well); (AMs: 1.0 x 10 ⁷ total) Dose/Concentration: 100, 500 µg/mL Time to Analysis: 2, 8, 24h | Viability: Over 90% of HBEC were viable after a 24 hour exposure of up to 500 µg/mL of PM. AMs incubated with and without 100µg/mL saw no significant difference in viability. Cytokine mRNA: TNF-α, GM-CSF, IL-1β, IL-6, LIF, OSM and IL-8 mRNA expression increased in co-culture with 100 µg/mL at 2 and 8h. In AMs, TNF-α, IL-1β, IL-6 mRNA expression increased with 100 µg/mL at 2h. IN HBECs, IL-1β and LIF increased with 100 µg/mL at 2h. HBECs added to AMs exposed to PM ₁₀ , further increase in mRNA of IL-1β, LIF and IL-8. Cytokine Protein: In co-culture and AMs, significant increase in protein production of GM-CSF, IL-8, IL-1β, IL-6 and TNF-α in dose-dependent manner. GM-CSF and IL-6 production significantly higher in co-culture then AM or HBEC alone. Bone Marrow: Co-culture instillation of supernatants increased circulating band cell counts at 6 and 24 h with 100 µg/mL. |
| Reference: Fujii, T. Hayashi, S. Hogg J.C. LDH: Increase at 72 h with 56.52 and 75.36 µg/mL. Oxidative Stress: A decrease in MDF activity was observed at all exposure levels at 24, 48, and 72 h (72-h < 5 % of control). MDA levels showed increase concentration after 72 h, both LC10 and LC50. LC10 and LC50 saw an increase in SOD activity at 24 h; LC50 saw a decrease in activity after 48 and 72 h. 8-OHdG and PARP exhibited increases at all time points with LC10 and LC50. Inflammatory Response: Increases of TNF-α concentration was exhibited at 24 h at LC50, and at 48 h and 72 h at LC10 and LC50. iNOS activity increase at all time points at LC10 and LC50. NO concentration exhibited increases at all time points after exposure to LC10 and LC50. |
| Reference: Geng H et al. (2005, 096689) Species: Rat Strain: Wistar Tissue/Cell Type: Lung macrophages | BPM: Blowing PM _{2.5} NPM: Non Blowing Normal PM _{2.5} Particle Size: PM _{2.5} PM collected from Wuwei City, Gansu Province, China (Blowing days correspond to desert storm days) | Route: Cell Culture Dose/Concentration: 0, 33, 100, 300 µg/mL Time to Analysis: 4h | NOTE: Unless otherwise noted, results are identical for BPM and NPM. Cytotoxicity: Dosages greater than 150 µg/mL decreased cell viability. Plasma Membrane Fluidity: Dose-dependent decrease had no effect on membrane lipid hydrophilic region. Plasma Membrane Permeability: LDH enzyme activity and extracellular AP activity increased dose-dependently, indicating increased membrane permeability, but this was only statistically significant at 300 µg/mL dose. NPM may affect some parameters at 100 µg/mL. Overall, NPM induced a slightly higher increase than BPM. Intracellular Ca²⁺: A dose-dependent increase was observed. Lipid Peroxidation (TBA): An increase was observed only at 300 µg/mL. Antioxidant (GSH): A decrease was observed only at 300 µg/mL. |
| Reference: Geng H et al. (2006, 097026) Species: Rat Strain: Wistar Tissue/Cell Type: Lung macrophages | DPM: dust storm samples NPM: normal PM Particle Size: PM _{2.5} PM collected from Baotou City, Inner Mongolia, China in March 2004 | Route: Cell Culture Dose/Concentration: 0, 33, 100, 300 µg/mL Time to Analysis: 4h | NOTE: Unless otherwise noted, results are identical for BPM and NPM Cytotoxicity: MTT reduction assay revealed a significant decrease in cell viability at 150 µg/mL and 300 µg/mL. LDH enzyme activity significantly increased at 150 and 300 µg/mL. GSH levels: Significant decreases were seen in cellular GSH levels and increases in TBARS levels in both groups with a 300 µg/mL dose. Plasma Membrane Activity: In the plasma membrane, Na,K-ATPase were significantly inhibited. Ca ²⁺ + Mg ²⁺ + -ATPase were unaffected. Plasma Membrane Lipid Fluidity: Results indicate that DPM could increase the surface fluidity of membrane lipid. Intracellular Ca²⁺: A dose-dependent increase in free intracellular Ca ²⁺ levels was observed. |
| Reference: Ghio et al. (2005, 088272) Species: Human Cell/Tissue Type: BEAS-2B | FAC: ferric ammonium citrate (component of ROFA) VOSO ₄ : vanadyl sulfate (component of ROFA) Particle Size: NR | Route: Cell Culture Dose/Concentration: 100 µM FAC - preexposed before metal compounds or oil fly ash 50 µM VOSO ₄ - preexposed before metal compounds or oil fly ash 100 µg/mL ROFA Time to Analysis: 0-1h, 4h | IRE DMT1: FAC increased mRNA and protein expression for -IRE DMT1. VOSO ₄ decreased mRNA and protein expression for -IRE DMT1. +IRE DMT1 unaffected by any treatment. Metal transport: Uptake of iron increased after pre-exposure to FAC and decreased after pre-exposure to VOSO ₄ . Pre-exposure to FAC again increase the uptake of both iron and vanadium. VOSO ₄ induced opposite effect, decreasing Fe uptake. ROS: Increased acetaldehyde, indicating increased oxidative stress. ROS decreased with FAC pretreatment. ROS increased with VOSO ₄ pretreatment. |

Other particle types had no effect. After 24 h, LDH level was not statistically significant between particles tested and control. Cytokines: Treatment with Montana ultrafine particles resulted in a significant production increase of TNF-α. MIP-2 showed increases in all the fine and ultrafine treatments, with Montana ultrafine and W. Kentucky fine PM showing the highest increases. IL-6 increased with Montana ultrafine particles although there was some variability and the increases were not statistically significant. |
| Reference: Gilmour et al. (2005, 087410) Species: Human Cell/Tissue Types: monocyte derived macrophages, HUVECs, A549, 16HBE | PM ₁₀ : Collected from the Marylebone and Bloomsbury monitoring sites in London, UK Particle Size: PM ₁₀ | Route: Cell Culture Dose/Concentration: 50 µg/mL Time to Analysis: 4h, 6h, 20h | IL-8: PM ₁₀ at 50µg/mL induced a significant increase in IL-8mRNA and protein expression in PMM and 16HBE at 6 and 20h. A less substantial increase was also observed in A549. Procoagulant Activity: PM ₁₀ induced a significant decrease in macrophage mediated clotting time in 16HBE. Other cell types were unaffected. Annexin V Binding: At 100 µg/mL, PM ₁₀ induced a significant increase in binding macrophages at 4 and 20h. There was no effect at 50 µg/mL. Tissue Factor mRNA Expression: Expression was increased in macrophages at 6 h only. tPA Expression: mRNA expression decreased at 6h. Protein expression decreased at 4 h and 20 h in a dose-dependent manner. TF Expression: TF mRNA expression increased in a dose-dependent manner at 6 h in HUVECs. Protein levels also increased at 4 h but declined to basal levels by 20h. |
| Reference: Gilmour et al. (2003, 096959) Species: Human Cell/Tissue Type: A549 | PM ₁₀ : Collected from the Marylebone and Bloomsbury monitoring sites in London, UK TSA H2O2 NAC Mannitol Provided by Sigma Chemical, Poole, UK or GIBCO-BRL, Paisley, UK Particle Size: PM ₁₀ | Route: Cell Culture Dose/Concentration: PM ₁₀ : 100 µg/mL; TSA: 100 ng/mL; H2O2: 200µM; NAC and Mannitol: 5 mM Time to Analysis: 24h | IL-8: PM ₁₀ , TSA and H2O2 treatment induced an increase of IL-8. Concomitant exposure of TSA with PM ₁₀ or H2O2 significantly increased IL-8 release when compared to PM ₁₀ or H2O2 alone. IL-8 mRNA expression with PM ₁₀ or H2O2 exposure and TSA coinubation caused significant increases. Silver staining of PCR products indicated that the IL-8 gene promoter was associated with acetylated H4 following TSA, PM ₁₀ and TNF treatment. H4: PM ₁₀ exposure significantly increased acetylation levels of H4 over controls. Increased acetylated H4 was mediated by PM ₁₀ in a dose-dependent manner. Treatment with PM ₁₀ and H2O2 increased HAT activity associated with H4 by 245% and 166% respectively. Significant increases in acetylation of H4 following treatment of cells with TSA, PM ₁₀ and H2O2 for 24 h was observed. PM ₁₀ induced HAT activity was significantly decreased in the presence of NAC and mannitol. Nuclear presence of HDAC2 protein was significantly reduced by exposure to both HDAC inhibitor and PM ₁₀ . There was a decreasing trend in HDAC2 gene expression following TSA and PM ₁₀ treatment. NF-kB: The activation of the transcription factor NF-kB was enhanced following the inhibition of HDAC with TSA and by treatment with |

| Reference: Graff DW et al. (2007, 156488) Species: Human Cell/Tissue Type: HAEC | PM -UF: ultrafine -F: fine -C: coarse Particles collected from Seattle, WA (-S), Salt Lake City, UT (-SL), Phoenix, AZ (-P), South Bronx, NY (-SB), Hunter College, NY (-H), Sterling Forest, NY (-SF) Particle Size: UF: < 0.1 μm ; F: 0.1- 2.5 μm ; C: 2.5-10 μm | Route: Cell Culture Dose/Concentration: 250 $\mu\text{g}/\text{mL}$ Time to Analysis: 6h, 24h | Gene Expression: PM-UF, PM-F, and PM-C both upregulated and downregulated genes in the HAECs though downregulation was far more common for all the three PM fractions. PM-F affected the greatest number of transcripts, followed by the UF and C fractions. IL-8: mRNA expression increased, with PM-F-S having the greatest impact. Aluminum, strontium, manganese and potassium were highly associated with expression. Wood combustion was moderately associated. HOX-1: mRNA expression increased, with PM-F-SF having the greatest impact. Potassium, manganese, strontium and wood combustion were highly associated with expression. Aluminum and vanadium were moderately associated. |
| Reference: Gualtieri M et al. (2005, 097841) Species: Human Cell Type: A549 | TD: Tire debris extracted in methanol, constituent of PM ₁₀ (generated by spinning a new automotive tire against abrasive surface) Particle Size: 10-80 μm | Route: Cell Culture Dose/Concentration: 10, 50, 60, 75 $\mu\text{g}/\text{mL}$ Time to Analysis: 24, 48, 72h | Cytotoxic Effect: Treated cells presented inhibitory effect on reduction of MTT which appeared to be dose and time-dependent. A statistically significant reduction was observed at 48 and 72 h. Trypan blue showed a significant PM lethality as well as a dose-dependent increase in mortality. DNA Damage: At 24 and 72 h, DNA damage increase dose dependently in damaged and ghost cells. Cell Cycle Analysis: At 24 h, TD extract-treated cells presented a significant increase in the percentage of cells in G1 phase when compared with control. This increase was associated with a decrease in the percentage of cells in S phase. At 48 and 72 h, the increase in percentage of cells in G1 was associated with a decrease in the percentage of cells in both S and G2/M phases. Cells exposed to TD extracts presented changed morphology. Modifications most obvious at 72 h. The highest dose produced increased vacuolization in cytoplasm and apoptotic nuclear images. |
| Reference: Hetland et al. (2005, 087887) Species: Rat Gender: Male Strain: CrI/Wky Cell Type: AMs | PMC = Coarse PMF = Fine -A = Amsterdam -L = Lodz -R = Rome -O = Oslo Coexposures PAH, Fe, Al, Zn, Cu, V Particle Size: PMC: 2.5-10 μm ; PMF: 0.2-2.5 μm | Route: Cell Culture (1.5x10 ⁶ cells/well) Dose/Concentration: 50, 100 $\mu\text{g}/\text{mL}$ PM Time to Analysis: 20h | IL-6: PMC from all cities exhibited increases in IL-6 release with spring and summer roughly equal and both inducing higher levels than the winter PMC. For the Spring and Summer samples, PMC-L exhibited the highest IL-6 releases (440% and 460% respectively) followed by Rome, A'dam/Oslo, and Oslo/A'dam. For the winter samples, Rome and Amsterdam induced higher IL-6 levels (340% and 300% respectively) than Lodz and Oslo (165% and 160%). The fine fractions did not induce any significant cytokine release. TNF-α: PMC from all cities increased TNF- α release with 50 $\mu\text{g}/\text{mL}$ generally inducing a slightly higher increase than 100 $\mu\text{g}/\text{mL}$. Constituent Correlation: Levels of Fe, Al, Zn, Cu and V as well as PAH (total and fractions) showed no correlation with IL-6 release. Endotoxin Correlation with IL-6 release: A confirmatory test revealed no correlation. |

| Reference: Hutchison et al. (2005, 097750) Species: Mouse Cell Line: J774.1A | PM ₁₀ : Samples collected for 7d during closure (-C) and reopening of steel plant (-R) PMT: PM total (aqueous sonicate) PMS: PM soluble aqueous PMI: PM insoluble aqueous Particle Size: PM ₁₀ | Route: Suspension Dose/Concentration: 500 μ l (estimated concentrations of 112, 143, 156, 180, 233, 255 μ g/1ml water) Time to Analysis: 4h | Particle Characterization: Reopening of the plant showed a significant increase in the total and acid extractable metal content of PM. Aqueous extractable metal content did not change. Soluble zinc, copper and manganese also increased significantly post reopening. Iron was the most abundant in acid extractable metals and increased greatly at the reopening. TNF-α: PMT-R and PMT-C induced a statistically significant increase. Treatment with chelation agent reduced effect to control levels. |
| Reference: Imrich A et al. (2007, 155859) Species: Rat Gender: Female Age: 12-14wks Cell Type: AM | UAP: SRM 1649 (positive control) TiO ₂ : Particle control CAPs (Boston, MA) All cells primed with LPS Coexposure with NAC, dimethylthiourea (DMTU), H ₂ O ₂ or catalase Particle Size: CAPs: \approx 2.5 μ m; UAP: PM _{2.5} ; TiO ₂ : \sim 1 μ m | Route: Cell Culture (2 X10 ⁵ cells/well) Dose/Concentration: Caps 100 μ g/mL; UAP: 50 or 100 μ g/mL; LPS 250 ng/mL; NAC, DMTU: 2, 10, 20mM; Catalase: 1, 5, 10mM; H ₂ O ₂ 0-50 μ m/hr Time to Analysis: 18-20h | TNF: DMTU at 20mM reduced TNF in LPS-primed cells in control and UAP-treated groups. NAC at 20mM reduced TNF release but this was not statistically significant. Catalase significantly inhibited TNF in control and UAP-treated groups. CAPs (especially the insoluble portion) significantly increased TNF unless co-exposed with NAC, DMTU or catalase. All three reduced levels back to around basal levels. DMTU was particularly effective at diminishing TNF release. H ₂ O ₂ increased TNF release in CAPs-exposed cells. TiO ₂ had no increased ability to induced cytokine release when mixed with H ₂ O ₂ . Cell Death: Viability decreased substantially when exposed to H ₂ O ₂ + CAPs. The soluble fraction of CAPs showed to be more effective with H ₂ O ₂ than the insoluble portion. TiO ₂ had no significant effect. NO: Some CAPs induced slight increases when mixed with H ₂ O ₂ . No difference was observed between soluble and insoluble portions of CAPs. DFO: DFO at 0.05mM completely inhibited oxidation induced with soluble CAPs + H ₂ O ₂ . Insoluble CAPs + H ₂ O ₂ was also DFO-sensitive. DFO was ineffective against the insoluble CAPs induction of TNF and MIP-2. |
| Reference: Ishii et al. (2004, 088103) Species: Human Cell Type: A549 (collected from 6 lobectomy or pneumonectomy smokers), HBEC | EHC-93:PM ₁₀ (obtained from Environmental Health Directorate, Ottawa, Ontario, Canada) Particle Size: PM ₁₀ | Route: Cell Culture (1x10E7 cells) Dose/Concentration: 100 μ g/mL Time to Analysis: 3, 6, 24h | Cytokines: TNF- α , IL-1 β , GM-CSF, IL-6, and IL-8 levels were significantly increased in A549 cells. mRNA Expression: MCP-1, ICAM-1 and IL-8 mRNA expression increased in untreated AM supernatants at 3h. Only the MCP-1 levels were statistically significant at 3h. Levels declined by 6h. When A549 cells were exposed to PM ₁₀ exposed AM, levels of RANTES, TNF- α , ICAM-1, IL-1 β , and LIF increased. Except for RANTES mRNA, these differences were less in the 6h samples. VEGF increased as well, but this increase was not statistically significant. TNF-α and IL-1β-neutralizing Antibodies: IL-1 β antibody alone or in combination with TNF- α significantly reduced expression of all eight mRNAs. Combinations for some mRNAs reduced expression by up to 1/2. This effect was not observed when A549 was treated with the control AM. Transcription Factor Binding Activity: Binding of AP-1 and Sp1 increased when A549 treated with supernatants from PM ₁₀ -exposed AM, but not from control AM. |

|--|---|--|--|
| Reference: Jalava et al. (2007, 096950) Species: Mouse Cell Type: RAW 264.7 | Urban background PM PM ₁₀ , PM _{2.5} , and PM _{0.2} collected from 6 European cities during different times of the year from October 2002 to July 2003: -D: Duisburg (Fall) -P: Prague (Winter) -A: Amsterdam (Winter) -HR: Helsinki (spring), -B: Barcelona (spring) -AT: Athens (summer) Particle Size: PM ₁₀ : 2.5-10 μm ; PM _{2.5} : 0.2-2.5 μm ; PM _{0.2} : < 0.2 μm | Route: Cell Culture (5 X10 ⁵ cells/mL) Dose/Concentration: 15, 50, 150, 300 $\mu\text{g/mL}$ Time to Analysis: 24h | PM Characterizations: The highest mass concentrations of PM ₁₀ and PM _{0.2} were measured in Athens. Prague had the highest PM _{2.5} concentrations. NO: All PM fractions induced statistically significant NO production in macrophages. PM _{2.5} -P and PM _{2.5} -AT produced significantly larger responses, though all samples at 150 and 200 $\mu\text{g/mL}$ induced statistically significant production. When compared to the other PM _{0.2} samples, -P and -HR produced significantly larger responses. Cytokines: PM ₁₀ showed average cytokine production to be 7.8 fold and 83 fold for TNF- α , and 4.4 fold and 530 fold for MIP-2 when compared to PM _{2.5} and PM _{0.2} respectively. PM ₁₀ induced statistically significant increases in production of TNF- α , MIP-2 and IL-6. PM _{2.5} , with exception of Prague, caused significant increases in cytokines. PM _{0.2} -A and -AT showed small yet statistically significant increases in TNF- α . An increase in MIP-2 was observed with -P and -HR. IL-6 increased significantly with PM ₁₀ and slightly with PM _{2.5} . In the PM _{0.2} range, only the -A and -AT samples caused a small, statistically significant TNF- α production. MIP-2 production was only detected from the -P and -HR samples. PM _{0.2} effects on IL-6 response were negligible. Cytotoxicity: The average cytotoxicity of PM ₁₀ and PM _{2.5} were roughly equal, but PM _{0.2} were less cytotoxic with the exception of -P. The dose-response trends for most of the samples were linearly declining, with PM ₁₀ and PM _{2.5} exhibiting statistically significant declines in viability. |
| Reference: Jimenez et al. (2002, 156610) Species: Human Cell Type/Line: A549, THP-1, Mono Mac 6 (DSMZ) | PM ₁₀ : Collected from London and Edinburgh air particulate monitoring stations. TiO ₂ UFTiO ₂ Both fine and ultra fine TiO ₂ fractions obtained from Tioxide Europe (London, UK) and Degussa-Huls (Cheshire, UK) Particle Size: PM ₁₀ , TiO ₂ : 200nm; UFTiO ₂ : 20nm | Route: Cell Culture (110,625 cells/well) Dose/Concentration: PM ₁₀ , TiO ₂ , UFTiO ₂ : 100 $\mu\text{g/mL}$; TNF- α : 10ng/mL Time to Analysis: 4h | NF-kB and AP-1 DNA Binding: NF-kB DNA binding increased in PM ₁₀ and TNF- α exposed macrophages by 9.5 and 12 fold. NF-kB activity remained unaltered in TiO ₂ and UFTiO ₂ exposed macrophages. IL-8: Cells treated with PM ₁₀ conditioned media increased transcription binding of NF-kB to IL-8 promoter sites. Increases were observed in gene expression after exposure to TNF- α and PM ₁₀ . TiO ₂ or UFTiO ₂ had no effect. Increases observed in IL-8 production with PM ₁₀ . IL-8 Promoter CAT Activity: PM ₁₀ media increased CAT expression by 65% over control. No differences observed with TiO ₂ or UFTiO ₂ media. Neutrophil Chemotaxis: PM ₁₀ conditioned media induced a 2.3 fold increase compared to control. TNF-α and IL-1β Production: PM ₁₀ media increased TNF- α and IL-1 β production. No increases were observed in TiO ₂ and UFTiO ₂ media. |

| Reference: Katterman ME et al. (2007, 096358) Species: Rat Cell Type/Line: RLE-6TN (Alveolar Epithelial Cell Line) | PM: Oils: OAAF, Oil Q, Oil I II, NF2 PM: Coal Germany and Ohio Diesel particulates: ZODDA (doped with Zn), ZSDDA (doped with Zn and S): S: PMs washed in solution; F: Fresh samples; L: Leached Al ₂ O ₃ , Fe ₂ O ₃ , SiO ₂ , TiO ₂ , ZnO also tested Particle Size: NR | Route: Cell Culture (cytotoxicity: 50,000 cells/well; SEM: 25,000 cells) Dose/Concentration: Oils 0.2mg/mL; Coals 0.7mg/mL; Diesel 0.01mg/mL; Al ₂ O ₃ 0.5mg/mL; Fe ₂ O ₃ 0.7mg/mL; SiO ₂ 0.7mg/mL; TiO ₂ 0.7mg/mL; ZnO 0.05mg/mL Time to Analysis: 24h | Metabolic Activity: For oils comprised of 3/4 fresh and 1/4 leached, metabolism decreased. Coals (fresh and leached) had no effect. ZODDA-F and ZSDDA-F both induced decreases in activity. ZSDDA-L had no effect. Cellular Morphology: PM-S had a minimal effect. PM-F induced widespread cell damage. Constituent Differences between PM-F and PM-L: In oil samples Cu, Ti and Ca salts were removed upon washing. Fe, Al, Si remained constant. Grinding Effects: Coal toxicity increased upon grinding, whereas diesel PM toxicity decreased upon grinding. Metal Oxide Effects: Only SiO ₂ , and ZnO (much higher at lower concentrations than other metal oxides) decreased metabolic activity. Fresh, washed and sonicated samples exhibited similar results. Grinding only affected TiO ₂ (increase) and ZnO (decrease). |
| Reference: Kendall et al. (2004, 156634) Species: Human Tissue Type: BALF (obtained by bronchoscope from 6 nonsmokers and 3 smokers) | PM _{2.5} sample sites; 2 schools in Bronx, NY, 6 background urban, 6 urban roadside. Sampling occurred 24h/day for 12d. Particle Surface Chemistry: 79-87% carbonaceous material (Ch, COO, C-(O,N)), 10-17% O (O1s), 1.5-4% N (NH ₄ ⁺ , N-C, NO ₃ ²⁻), 0.6-1% S, and 0.3-2 % Si. Only NO ₃ - higher in roadside samples. NH ₄ and NO ₃ - correlated with NO and NO _x in air but not NO ₂ . Particle Size: PM _{2.5} | Route: BALF treatment Dose/Concentration: 5-10ml of 0.5M NaCl or BALF Time to Analysis: Filters treated with BALF for 4h | Saline Washing: Removed particles and decreased NH ₄ , NO ₃ , O and S relative to C1. BALF treatment (XPS): PM _{2.5} surfaces interacted strongly with BALF within hours of contact. Specific surface components of PM _{2.5} immersed in BALF were desorbed while biomolecules from BALF were adsorbed to particles. N-C on the PM surface increased 3 fold for smokers and 4 fold for nonsmokers (range 1.4-7.4). This is most likely related to protein-like adsorption on PM. Treatment also induced a slight increase in COO and decreases in NH ₄ , NO ₃ , O and S. ToF-SIMS - Organics: Particle loading and surface hydrocarbons showed a linear correlation. Loss of hydrocarbons from PM _{2.5} surface averaged 55% (10-75) after undergoing saline and BALF washes. In only 3/12 samples BALF removed less hydrocarbon. BALF treatment increased the amino acid and phospholipid content of the PM _{2.5} surface. ToF-SIMS - Inorganic: Saline washing appeared to increase Al and Si but with extreme variability; this increase was not statistically significant. Both saline and BALF washing decreased NH ₄ and Na levels to a similar extent. BALF washing did not affect Al or Si. |
| Reference: Kim et al. (2005, 088454) Species: Human Cell Type/Line: BEAS-2B | Zn ₂ ⁺ Particle Size: NA | Route: Cell Culture Dose/Concentration: 15, 50, 100 μmol Time to Analysis: 1-20h | Cell Viability: At 50μM for 20h, no apoptosis was induced. IL-8: At 12h, IL-8 increased in dose-dependent manner. At 15 or 50μM, Zn ₂ ⁺ increased protein 1.6 and 4.6 fold respectively. IL-8 mRNA expression increased dose-dependently, reaching statistical significance at 2 h and continuing until 4h. EGFP (adenoviral IL-8 promoter): Levels increased 2.4 fold with 50μM Zn ₂ ⁺ . Proteases: With 50μM Zn ₂ ⁺ , phosphorylation of MAPKs ERK, JNK and p38 increased by 15min and continued increasing up to 2h. Pre-exposure of inhibitors of MEK, JNK, before Zn ₂ ⁺ exposure caused inhibition of Zn-induced IL-8 mRNA and protein production. Inhibitor of p38 had no effect. Dephosphorylation of ERK and JNK was partially inhibited with exposure to Zn ₂ ⁺ . |

| Reference: Kleinman et al. (2003, 087938) Species: Rat Strain: Wistar, Fischer 344 Age: 22-24m, 10wks Cell Type/Line: AMs | UF1: Utrecht 1 Fine (urban freeway) UC1: Utrecht 1 Coarse UF2: Utrecht 2 Fine (urban, freeway, light industrial) UC2: Utrecht 2 Coarse SRM 1650 SRM 1648 Particle Size: UF1: 0.2-2.5 μm ; UC1: 2.5-10 μm ; UF2: 0.2-2.5 μm ; UC2: 2.5-10 μm | Route: Cell Culture (10^5 cells/well at 10^6 cells/mL) Dose/Concentration: 1.2 to 1200 ng/ 10^6 cells Time to Analysis: 4, 18h | Macrophage PMA-stimulated respiratory burst activity: SRM 1648 and 1650 induced dose-dependent decreases approaching 0 at 50 - 100 $\mu\text{g}/10^6$ cells. Large dose-dependent decreases from old rat AMs exposed to fine PM exposure were followed by young rat AMs exposed to fine PM. However, no age-related effects were statistically significant. Free radical production: All coarse particles depressed free radical production in a semi-dose-dependent manner, with UC2 exhibiting more potency than UC1. Both fine particles also showed dose-dependent responses but UF1 and UF2 responses were greater than the control at 3 $\mu\text{g}/10^6$ cells. PM Characterization: Ratios between coarse and fine PM were similar for metals tested (Al, Fe, Mn, Zn). Al was higher in coarse samples and Zn higher in fine PM, although large variability was observed. Fe and Mn results were roughly equivalent for all samples. |
| Reference: Kocbach, A. Namork, E. Schwarze, P.E. 2008 Species: Human Cell Type/Line: THP-1 | PMW: Wood smoke particles Collected from conventional Norwegian wood stove burning birch PMT+: Traffic-derived particles Collected from road tunnel in winter when studded tires were used PMT-: Traffic-derived particles Collected from road tunnel in summer without studded tires DEP: SRM2975 Porphyr: fine grain syenite porphyry (prepared by SINTEF, Trondheim, Norway) Polymyxin B Sulphate (endotoxin inhibitor) Particle Size: PMW, PMT, DEP: NR; Porphyr 8 μm (mean) | Route: Cell Culture (1,000,000 cells/mL) Dose/Concentration: 30-280 $\mu\text{g}/\text{mL}$ Time to Analysis: 2, 5, 12h | Particle Characterization: PMT+ contained a high mineral particle content. PMT- contained carbon aggregates, organic carbon and polycyclic aromatic hydrocarbons (PAH). PMW and DEP contained carbon aggregates. PAH content of PMW was greater than DEP. Porphyr was not included in the analysis. Cytokines: PMT \pm induced releases of TNF- α , IL-1 β , and IL-8 with 30 or 70 $\mu\text{g}/\text{mL}$. PMW similarly induced TNF- α and IL-8. DEP induced IL-1 β and IL-8. Porphyr induced IL-8 increases. IL-4, IL-6 and IL-10 were unaffected. Overall, the order of effective cytokine induction from most to least effective was PMT \pm , PMW, DEP, and Porphyr. mRNA expression of TNF- α , IL-1 β , IL-8, and IL-10 increased with 140 $\mu\text{g}/\text{mL}$ of PMT \pm and slightly for PMW. LDH: PMT \pm induced small but statistically significant increases at low doses. DEP increased LDH at 280 $\mu\text{g}/\text{mL}$ only. Polymyxin B Sulphate: The endotoxin inhibitor significantly inhibited LPS-induced cytokine release by 80-90% and reduced PMT \pm induction by 50-60%. Organic Extraction: PMT+ washed and native particles showed equivocal induction of cytokine release. PMT+ organic extract had no effect. PMT- and PMW organic extracts significantly increased TNF- α and IL-8. Washed particles induced less significant increases of IL-8. DEP organic extract had no effect. |
| Reference: Kristovich R et al. (2004, 087963) Species: Human Cell Type/Line: HUVEC, HPAEC, HPMVEC, HPBMC | CP: carbon particle (carbonaceous negative image of zeolite) CFE: C/Fe particulate (synthesized) CFE+: C-Fe/F-Al-Si particulate (synthesized) CFA: Coal Fly Ash (Coal-fired power plant, NOS) DEP: (exhaust pipe of diesel powered truck) CP, CFE, CFE+ approx 1 μm (resembling zeolite) Particle Characterization (Surface chemistry): CP = 88% C, 1% Si, 10% O, 1% N. CFE = 80% C, 2% Fe, 2% Si, 16% O. CFE+ = 20% C, 6% Al, 3% Si, 50% F, 6% O, 11% N, 4% Na. CFA = 25% C, 3% Fe, 13% Al, 17% Si, 41% O, 1% N. DEP = 70% C, 3% Fe, 24% O, 1% N, 2% S. Particle Size: CP, CFE, CFE+: approximately 1 μm (resembling zeolite); CFA: < 2 μm ; DEP: 150nm | Route: Cell Culture (4x10E6 cells/well) Dose/Concentration: CP: 5-50 $\mu\text{g}/\text{cm}^2$; CFE: 2.5-25 $\mu\text{g}/\text{cm}^2$; CFE+: 2.5-25 $\mu\text{g}/\text{cm}^2$; CFA: 10-100 $\mu\text{g}/\text{cm}^2$; DEP: 2.5-25 $\mu\text{g}/\text{cm}^2$ Time to Analysis: 4, 8, or 24h | Cytotoxicity: CP exhibited no effects. DEP and CFE exhibited intermediate toxicities in the range of 50-70 $\mu\text{g}/\text{cm}^2$. No toxicity was apparent when treated with CFA (up to 200 $\mu\text{g}/\text{cm}^2$) or synthesized C particulates. Endothelial Activation: ICAM-1, VCAM-1, and E-selectin were activated dose-dependently by DEP, CFE, and CFE+. No effects observed for CFA or CP. These effects were not the result of endotoxin release. Individual Variability: Donors (humans) showed variability in responses especially for CFA. 3/9 had a medium response negated by ND responses in 6/9. |

| Reference: Kubatova, A. Dronen, L.C. Picklo, M.J. 2006 Species: Rat, Human Cell Type/Line: RAW 264.7 (rat), BEAS-2B (human) | PMW: Wood Smoke Collected from airtight wood stove burning hardwoods -P: Polar (fraction extracted from 25-50 C) -MP: Mid Polar (fraction extracted from 100-150 C) -NP: Nonpolar (fraction extracted from 200-300 C) -C: P + MP + NP Particle Size: NR | Route: Cell Culture (RAW 264.7: 10 ⁶ cells/mL; BEAS-2B: 10 ⁵ cells/mL) Dose/Concentration: 50, 100, 200 µg/mL Time to Analysis: 12h | GSH: PMW-MP and PMW-NP induced GSH depletion substantially in a dose dependent manner starting at 50 µg/mL in both cell types. DMSO had no effect. Cytotoxicity: PMW-MP and PMW-NP increased cytotoxicity at 200 µg/mL in RAW 264.7. BEAS-2B was unaffected. Particle Characterization: PMW-MP contained higher concentrations of oxy-PAHs, disringyls, syringylguaiacyls and PAHs. oxy-PAHs include 9-fluorenone, 1-phenalenone, 9,10-anthraquinone and hydroxycadalene. PAHs included phenanthrene, fluoranthene and pyrene. Effects of Individual Components of PMW-MP on GSH: 1,8-dihydroxy-9-10anthraquinone and 9,10-phenanthraquinone depleted GSH. 9,10-anthraquinone, anthrone, 1-hydroxypyrene increased GSH. Phenanthrene, 1-methylpyrene, 9-fluorenone and xanthone had no effect. |
| Reference: Kubatova et al. (2004, 087986) Species: Monkey Cell Type/Line: African green monkey kidney cells designated COS-1 (CV-1 cells with origin -defective mutants of SV40), E coli PQ 37 (SOS Chromotest) | DEP: Obtained from diesel bus PMW: Wood smoke particulates obtained from airtight wood stove burning hardwood HSF: Hot pressure fractionation -C: P + MP + NP -P: Polar -MP: Mid Polar -NP: Nonpolar OE: Organic Extraction -HNP: n-hexane nonpolar -MEP: methanol polar Particle Size: NR | Route: Cell Culture (10,000 cells/180 ul) Dose/Concentration: 0, 50, 100, 150, 200, 250, 300 µg/mL Time to Analysis: Cytotoxicity: 24h; Chomotest: 2h SOS | Cytotoxicity: PMW induced cytotoxicity in a dose-dependent manner. PMW-HNP induced low cytotoxicity, followed by PMW-C (intermediate) and PMW-MEP (highest). Levels above 25 µg/mL were cytotoxic. DEP-HNP induced cytotoxicity but was not dose-dependent. Results similar for all 3 fractions (highly variable). All fractions with concentrations higher than 100 µg/mL were cytotoxic. Extraction Water Temperature Effect: PMW was cytotoxic at temperatures over 50 C. DEP was cytotoxic at temperatures higher than 200 C. At 250 C, cytotoxicity between DEP and PMW was similar. At 300 C, PMW cytotoxicity declined and DEP stayed high, resulting in DEP inducing higher cytotoxicity than PMW. SOS Chromotest: β-Galactosidase formation increased, peaked at 200 C with DEP and declined to control at 300 C. Individual fractions showed linear dose response from 25-200 µg/mL with 150 C and 200 C extracts significantly higher. |
| Reference: Lee et al. (2005, 156682) Species: Human Cell Type/Line: A549 | MEP: Motorcycle Exhaust Particles (Yamaha Cabin engine, 95 octane unleaded gasoline, 150 rpm) MEPE: MEP Particle Free MEP 0.5 µm MEPE < 0.2 µm Particle Size: MEP 0.5µm; MEPE < 0.2 µm | Route: Cell Culture (1x10 ⁵ cells/well) Dose/Concentration: MEP 0.02, 0.2, 0.2, 2, 20 µg/mL; MEPE 20 µg/mL Time to Analysis: 24h | IL-8: MEP induced IL-8 at concentrations greater than 0.2 µg/mL. Levels increased 2fold at 24 h with 20 µg/mL. MEPE induced similar responses at 20 µg/mL. Induction of IL-8 mRNA expression was dose-dependent with MEP and MEPE. Cytotoxicity: Exposure to particles did not affect cytotoxicity. NFκB: MEP (20 µg/l) induced time-dependent activation for 2h and continued at same level for up to 6h. Pretreatment of PDTC (1mM) fully inhibited MEP induction. MAP Kinase: MEP induced time-dependent activation up to 30 min and stayed elevated for at least 60 min. ROI: MEP treatment induced a time-dependent increase in ROI for up to 1 h and then continued the at same level for up to 6h. |

HO-1, MnSOD Expression: RAW 264.7, THP-1 7h. RAW 264.7 cells exposed to whole DEP 16h. JNK Activation, IL-8 Production: THP-1 cells 30min, 16h. RAW 264.7 cells 90min. Cytotoxicity: RAW264.7, THP-1 18h. | GSH/GSSG Ratio: DEPM induced dose-dependent decrease in GSH/GSSG ratios in both cell lines. DEP induced decreases at comparable doses to DEPM. HO-1 Expression: Cells exhibited dose-dependent increases in HO-1 expression. HO-1 Expression in Murine RAW 264.7: VACES-F consistently induced HO-1 expression over a 9m period, whereas VACES-C was effective in inducing HO-1 during fall and winter. HO-1 induction positively correlated to higher OC and PAHs that were represented in VACES-F, but also seen with a rise in PAHs in VACES-C during winter months. MnSOD: At doses of 2.5 $\mu\text{g/mL}$, DEPM increased MnSOD in THP-1 cells. JNK Activation: DEPM dose-dependently increased JNK phosphorylation but did so without a change in the JNK expression level. DEP-exposed mouse RAW264.7 cells exhibited similar increases in JNK phosphorylation but without increasing JNK expression. IL-8: Exposure to DEPM elicited dose-dependent increase in IL-8 levels of THP-1 cells. |

|--|---|--|--|
| Reference: Li et al. (2002, 087451) Species: Human Cell Line: BEAS-2B, NHBE, THP-1 macrophages Species: Murine Cell Line: RAW 264.7, macrophages | DEPM (DEP methanol extract) DEPME (DEP methylene chloride extracts) DEPAL (DEPME aliphatic (hexane)) DEPAR (DEPME aromatic (hexane/methylene chloride)) DEPPO (DEPME polar (methylene chloride/methanol)) Particle Size: 0.05-1 μ m | Route: Cell Culture (10^6 cells/mL) Dose/Concentration: 0, 10, 25, 50, 100 μ g/mL Time to Analysis: 30, 60, 120min | <p>ROS: BEAS-2B cells demonstrated increased HE fluorescence, indicating increased ROS formation. THP-1 cells were unaffected.</p> <p>GSH/GSSG Ratio: DEPME dose-dependently decreased GSH/GSSG in THP-1 and BEAS-2B cells. Similar changes occurred with NHBE cells. THP-1 cells maintained a higher ratio of GSH/GSSG than BEAS-2B and NHBE cells.</p> <p>NAC on GSH/GSSG Ratio: Exposure to DEPME in the presence of NAC did not affect the GSH/GSSG ratio in BEAS-2B and NHBE cells. In THP-1 cells, NAC prevented a decline in the GSH/GSSG ratio.</p> <p>MnSOD and HO-1: THP-1, BEAS-2B and NHBE cells showed constitutive MnSOD expression and dose-dependent expression of HO-1 protein and mRNA. No change occurred in the expression of β-actin.</p> <p>DEPAL, DEPAR, DEPPO, CoPP on HO-1 Expression: DEPPO was more potent than DEPAR. DEPAL lacked activity for THP-1 and BEAS-2B cells. The potency of DEPPO was sufficient to affect cellular viability and HO-1. CoPP induction of HO-1 failed in THP-1 cells, but succeeded in BEAS-2B cells. However, it did not protect against the oxidizing effects of DEPME.</p> <p>JNK: JNK activation increased in DEP-exposed THP-1 and BEAS-2B cells. JNK isoforms were observed at doses of ≥ 25 μg/mL. In BEAS-2B cells a high rate of cell death diminished this response at 100 μg/mL. NHBE also showed increased JNK phosphorylation at doses 50 - 100 μg/mL.</p> <p>NAC on JNK: NAC led to inhibition of JNK activation.</p> <p>IL-8: THP-1 cells showed dose-dependent increases of IL-8. NHBE cells showed incremental increases followed by rapid decline at 100 μg/mL attributed to apoptosis. BEAS-2B cells responded to 10 μg/mL with increased IL-8, but cellular toxicity and cell death led to a drop in IL-8 production at higher doses.</p> <p>Cytotoxicity: Comparing cytotoxicity at 25 μg/mL DEP, BEAS-2B cells had a higher rate of cell death than THP-1 cells. BEAS-2B cells showed a significant rise in cell death at doses larger than 10 μg/mL. In THP-1 cells, it took doses of 25 μg/mL or more before significant increases occurred.</p> <p>In BEAS-2B, cell death began at 2h. In THP-1, increases in cell death prolonged for 8h or longer. NHBE cells also showed increase rates of cytotoxicity compared to macrophages. NAC in THP-1 interfered with a generation of cytotoxicity, but NAC did not have any decreasing effect on cell death in BEAS-2B or NHBE cells.</p> |

| Reference: Liu et al. (2005, 088304) 2005 Species: Human Cell Type: HPAECs | SE: Wood Smoke Extract (Generated using a stainless steel receptacle containing 100g of dry wood dust) Particle Size: NA | Route: Cell Culture Dose/Concentration: 40 $\mu\text{g/mL}$ Time to Analysis: 0-4h; Mitochondrial Membrane Destabilization: 0-60min; DNA Defragmentation: 0-6h; Cytotoxicity: 24h | Viability: SE exposure reduced cell viability dose-dependently. Reduction reached ~38% of control. Effect on Oxidative Stress/ Antioxidant Enzymes: SE caused an increase in ROS levels, in particular O ₂ ⁻ and H ₂ O ₂ in a time-dependent manner. Exposure to SE for up to 4 h caused a decrease in GSH levels in a time-dependent manner. Increased expression of Cu/Zn SOD mRNA and HO-1 mRNA was observed. Catalase or GPx mRNA expression was unaffected. Upregulation of Cu/Zn SOD and HO-1 occurred in a time-dependent manner Mitochondrial Translocation/ Caspase-Independent Apoptosis/DNA fragmentation: Exposure for up to 60 min caused an increase in the percentage of annexin V-FITC-pos cells but not PI-pos cells. At 4h, FDA-pos cells was unaffected. SE exposure caused a loss of mitochondrial membrane potential (indicated by the change in JC-1 fluorescence). Cytosolic bax levels increased after exposure for 1 or 2h and returned to basal level at 4 h after exposure. Levels of procaspase-3 and caspase-9 were unaltered by SE exposure after 4h. Procaspase-3 increased and caspase-9 decreased by H ₂ O ₂ exposure. SE exposure increased levels of AIF and EndoG (exposure up to 4 h). At 6h, increased DNA defragmentation was observed. Pre-treatment with caspase inhibitors (CMK and Z-VAD-FMK) failed to suppress SE-induced apoptosis. NAC: Treatment with NAC prevented ROS increase in cells exposed to SE for 60 min. NAC addition prevented the reduction of GSH by SE. NAC decreased nuclear levels of AIF and EndoG and completely reduced DNA-fragmentation. NAC alleviated the SE-induced reduced viability. GSH and DNA fragmentation were unaffected by NAC. |
| Reference: Long et al. (2005, 087454) Species: Human Cell Types: Human, Peripheral blood mononuclear cells (PBMCs) differentiated into MDMs (90-95 % CD14+) and T lymphocytes | Synthetic C and C/Fe particles (phenol and paraformaldehyde polymers on a zeolite template) C/Fe analysis Al 1.38 %, Si 0.33 %, Fe 0.46% Particle Size: 1 μm | Route: Cell Culture (5 x 10 ⁶ cells (2 mL /well) MDM s Dose/Concentration: 5 $\mu\text{g/cm}^2$ Time to Analysis: 2-24h | ROSs release: Oxidative burst form C/Fe maxes out at 20 min with no effect from C particles. Cellular particulate actions: C particulates were present within lysosomes with small clumps forming after 24 h outside of lysosomes with no evidence of organelle lysis and/or agglomeration. C/Fe particulates showed similar initial effects progressing at 24-h total organelle lysis extending to the outer cell membrane. T cell effects: No effects from C or C/Fe particles Medium Effect: Particle agglomeration appears to be a direct result of serum present within a cellfree medium Hydroxyl radical formation: C/Fe particles showed an order of magnitude of higher hydroxyl formation as compared to C particles |

| Reference: Ma et al. (2004, 088417) Species: Mouse Cell Line: JB6P+ (Epidermal Cell Line) | DEP: SRM 1975 Particle Size: 0.5 μm | Route: Cell Culture Dose/Concentration: Non-cytotoxic: 5, 10, 20 $\mu\text{g/mL}$; Cytotoxic: 0, 10, 20, 40, 80, 100, 160 $\mu\text{g/mL}$ Time to Analysis: 24, 48h; NF- κB and AP-1: 12h Phosphorylation of Akt: 5- 120 min. Effect of LY294002 on DEP: Cells pretreated with LY294002 (0 or 10 μM) for 30 min and then exposed to DEP for 0-60min. | Viability: Below 20 $\mu\text{g/mL}$, DEP had no effect. At concentrations greater than 20 $\mu\text{g/mL}$, DEP caused apoptosis. NF-κB and AP-1: DEP stimulated NF- κB activity at 5 and 10 $\mu\text{g/mL}$. At 20 $\mu\text{g/mL}$, NF- κB activity decreased, but was still greater than the control. DEP had no effect on AP-1 activity. PI3K/Akt Signaling Pathway: DEP induced phosphorylation of Akt on both Thr-308 and Ser-473. LY294002 (an inhibitor of P13K) blocked phosphorylation of Akt, p70/p85 s6 kinase and GSK 3b. LY294002 eliminated DEP-mediated phosphorylation of Akt. Inhibition of P13K by expressing p85 also blocked DEP-induced Akt phosphorylation. DEP induced phosphorylation on GSH-3B on Ser-9 without affecting tyrosine phosphorylation and enhanced phosphorylation of p70/p85 S6 kinase on Thr-389. DEP had no effect on phosphorylation of FKHR. SAPK/JNK Pathway: DEP slightly activated the pathway. Increased transient activation of MKK4 (a signal component of the SAPK/JNK pathway) and thus enhanced phosphorylation of SAPK/JNK. DEP promoted phosphorylation of c-Jun and ATF-2. DEP did not affect p38 MAPK or ERK phosphorylation. LY294002: Treatment with LY294002 (P13K inhibitor) eliminated DEP-induced NF- κB activity. A similar effect was observed with the use of another P13K inhibitor, wortmannin. TDZD-8 (GSK-3B inhibitor), D-JNKI(a JNK inhibitor), SB202190 (inhibitor for p38 MAPK) or PD98059 (inhibitor for MEK1) had little effect on DEP-mediated NF- κB activation. |
| Reference: Maciejczyk and Chen (2005, 087456) Species: Human Cell Type: BEAS-2B isolated from normal bronchial epithelium | CAPs: PM _{2.5} Collected via cyclone inlet on side of building in Tuxedo, NY. Weekdays 9-3 March 4 to September 5, 2003 Mass contributions of the Regional Sulfate, Soil, Oil: Combustions and Unknown/other categories to CAPs are: Regional Sulfate- 65%, Soil- 20%, Unknown/Other- 13% and Oil Combustion- 2%. Composition: * Regional Sulfate characterized by high concentrations of S, Si and organic carbon. * Soil characterized by high concentrations of Ca, Fe, Al and Si. * Oil-Combustion characterized by high concentrations of V, Ni and Se. Particle Size: PM _{2.5} | Route: Cell Exposure (subchronic exposures); Cell Culture (NF- κB) (9x10 ⁴ cells/well) Dose/Concentration: Ambient 13 \pm 9 $\mu\text{g}/\text{m}^3$ CAPS 109 \pm 178 $\mu\text{g}/\text{m}^3$ (air exposure); 300 μg PM/ml (culture) Time to Analysis: 24h | NF-κB: NF- κB response most notably correlated with V and Ni - elements associated with oil combustion source category (oil combustion makes up the group that is the smallest percentage of CAP mass). |
| Reference: Madden, M. C. Dailey, L.A. Stonehuerner, J.G. 2003 Species: Human Cell Type: NHBE | DEP(SRM 2975) Diesel Exhaust Extracts from a High load (HL ~ 75% engine load) or Load load (LL 0% engine load): Obtained from Caterpillar diesel engine, 4cyl, 4 stroke, model 3304 Particle Characterization: LL extract has greater amount of low-molecular-weight carbonyls (2-5 carbons). HL had more intermediate size carbonyls (6-9 carbons). Largest carbonyls analyzed (11-12 carbons) found in similar ratios in the two types of extract (number of carbons is indicative of differences in boiling points). Particle Size: NR | Route: Cell Culture Dose/Concentration: 0, 10, 50, 100, 250, 500 $\mu\text{g}/\text{well}$ Time to Analysis: 24h (after 2h of treatment, 0.5 ml of BEGM added to each well and cells incubated for an additional 22h) . | Cytotoxicity: -LL, -HL and SRM had no effect on LDH release. ⁵¹ Cr: Incubation of cells with -LL or SRM (10 to 500 $\mu\text{g}/\text{well}$) had no effect. 500 $\mu\text{g}/\text{well}$ of -HL induced a significant increase in ⁵¹ Cr release. IL-8: -HL induced a 5-fold increase in IL-8 at 500 $\mu\text{g}/\text{well}$. A decrease was observed at the highest dose of -LL extract. SRM did not significantly alter IL-8 production. PGE2: Production of PGE2 (inflammatory/immune mediator) increased in cells treated with HL extract at 500 $\mu\text{g}/\text{well}$. -LL had no effect. Stimulation with melittin caused -LL extract to have inhibitory effect on PGE2 at 500 $\mu\text{g}/\text{well}$. SRM had no effect. |

| Reference: Matsuo, M. Shimada, T. Uenishi, R. 2003 Species: Human Cell Type: NHBE, NHPAE, TIG-1, TIG-7 (normal human lung embryonic fibroblasts) | DEP: prepared at National Institute for Environmental Studies (Tsukuba, Japan) RDEP: residual DEP (after sequential extraction with hexane (NOS), benzene, dichloromethane, methanol, 1N ammonium hydroxide) Particle Size: 0.4 μ m (MMAD) | Route: Cell Culture (NHBE: 5x10 ⁴ cells/cm ² ; NHPAE: 3x10 ³ cells/cm ² ; TIG-1 and TIG-7: 3x10 ³ cells/cm ² ; Apoptosis: 2x10 ³ cells/cm ² ; ROS/NO: 2x10 ⁴ cells/cm ² ; Cytotoxicity Modulating Agent: 3x10 ⁴ cells/cm ² ; GSH: 3x10 ⁴ cells/cm ²) Dose/Concentration: 25, 50, 100, 200, 300, 400, 500 μ g/mL Time to Analysis: 1h | Cytotoxicity in NHBE: Both DEP and RDEP exhibited dose-dependent cytotoxicity at concentrations beginning from 50 μ g/mL and higher. RDEP was less cytotoxic than DEP. DEP exposure resulted in necrosis, not apoptosis. Comparative Cytotoxicity: The order of LC ₅₀ values (50% lethal concentration) was: NHBE (118 μ g/mL), NHPAE (137 μ g/mL), TIG (270 μ g/mL). NHBE's susceptibility was higher than the susceptibility of NHPAE and TIG cells. ROS/NO: DEP induced dose-dependent increases at 25 and 50 μ g/mL. Reduced Glutathione: DEP induced dose-dependent decreases. At 200 or 300 μ g/mL, GSH levels decreased by 55.2 or 97.3%, respectively. Antioxidant Effects: Various antioxidants either decreased DEP cytotoxicity (PMC, Ebselen, EUK-8) or had no effect on DEP cytotoxicity (SOD, catalase, GSH, α -tocopherol) Chelating Agents: DEP became less cytotoxic when ion-chelating agents were preincubated for 24h. No effect on DEP cytotoxicity was observed when chelating agents were administered to cells immediately after sonication. Endocytosis inhibitors: Decreased DEP toxicity was observed in a dose-dependent manner. |
| Reference: Matsuzaki, T. Amakawa, K. Yamaguchi, K. 2006 Species: Human Cell Type: Peripheral neutrophils Gender: Male and Female Age: 20-40yrs | DEP: generated from a 4JB1-type, 4 cyl Isuzu diesel engine me-DEP: methanol extract of DEP (40 % of DEP by dry weight) Particle Size: 0.4 μ m | Route: Cell Suspensions (5 X10 ⁵ cells/mL) Dose/Concentration: all me-DEP f-actin: 1, 5, 10 μ g/mL CD11b: 5, 10, 30 μ g/mL IL-8: 5, 10, 30 μ g/mL H2O2: 5, 10, 30, 60 μ g/mL MMP-9, LTB-4: 5, 10, 30, 60 μ g/mL Time to Analysis: f-Actin: 15min CD11b: 2h IL-8: 2 or 24h H2O2: 30min MMP-9, LTB-4: 2 or 24h | F-Actin: Treatment with me-DEP showed a dose-dependent increase in the f-actin content of neutrophils and this increase was significantly higher at 5 and 10 μ g/mL. CD-11b: Treatment increased CD-11b expression two-fold at 30 μ g/mL. IL-8: Minimal response was observed after 2h. A significant increase was observed (243%) at 24 h with 30 μ g/mL. LTB-4: At 2h, LTB4 increased to 115% and 119% with 30 and 60 μ g/mL me-DEP respectively. At 24 h with 60 μ g/mL me-DEP, LTB-4 increased to 153%. H2O2: Exposure to 30 and 60 μ g/mL of me-DEP induced large dose-dependent increases of 563% and 1220%, respectively. MMP-9: A significant increase at 2 and 24 h were observed. In both exposure periods, 30 μ g/mL induced larger increases than 60 μ g/mL. |
| Reference: Molinelli, A.R. Santacana, G.E. Madden, M.C. 2006 Species: Human Cell Type: NHBE, BEAS-2b (transformed bronchoepithelial cells) | PMH: PM ₁₀ extracts in hexane PMA = PM ₁₀ extracts in acetone of residue after hexane extraction -G: Guaynabo(Urban) and -F: Fajardo (Preservation Area), PR, USA 1999 Particle Size: PM ₁₀ PM ₁₀ extracts collected by Puerto Rico Environmental Quality Board | Route: Cell Culture (3x10 ³ cells/well) Dose/Concentration: NHBE exposed to 0-100 μ g/mL of PM ₁₀ BEAS-2B exposed to 10,100, 250 μ g/mL of PM ₁₀ Time to Analysis: 48h | Metal analysis: Hexane extracts Cu, V, Ni all higher in winter than summer. For hexane extracts within the same season, metal concentrations were higher in the Fajardo extracts. On the other hand, the acetone extracts from Guaynabo generally had higher metal concentrations than Fajardo. Cytotoxicity NHBE: The order of most to least toxic for PM extracted with hexane is: winter-G, winter-F, summer-G, summer-F. The order of most to least toxic for PM extracted with acetone is: summer-G, summer-F, winter-g. Cytotoxicity BEAS-2: For PM extracted with hexane, the cytotoxicity order is: winter-G, winter-F, summer-G, summer-F. The order for acetone extracted PM is: summer-G, summer-F, winter-F, winter-G. Effects trend similar to metal levels (no analysis). Summer extracts showed linear dose-response curves. Winter extracts exhibited more equivocal results, especially for Fajardo. Results suggest that NHBE cells are more sensitive than the BEAS-2B cells to PM extracts. |

| Reference: Moller et al. (2002, 036589) Species: Canine, Mouse Cell Type: Beagle-Dog Alveolar Macrophages (BD-AM), J774A.1 (from cell line BALB/c/NIH) | fTiO2 (origin NR) ufTiO2 (origin NR) ufP-G: carbon black (Printex-G, Degussa, Frankfurt, Germany) ufP90: carbon black (Printex90, Degussa, Frankfurt, Germany) ufEC90: elemental carbon (produced by electrical spark generator under standardized conditions with low impurities) DEP (SRM 1650) UrbD: Urban Dust (SRM 1649a) Particle Size: (in diameter) TiO ₂ : 220nm; ufTiO ₂ : 20nm; ufP-G: 51nm; ufP90: 12nm; ufEC90: 90nm; DEP: 120nm; UrbD: NR | Route: Cell Suspension Dose/Concentration: 10, 32, 100, 320 µg/mL Time to Analysis: 24h | Cytoskeleton of J774A.1: At doses of 32 µg/mL or less, the particles did not significantly influence relaxation and stiffness. fTiO ₂ and ufP90 had no effect at any dose. ufTiO ₂ at 320 µg/mL induced retarded relaxation and significant stiffening. ufEC90 induced dose-dependent retardation of relaxation and increased stiffening. DEP and UrbD induced similar results. Cytoskeleton of BD-AM: ufTiO ₂ and fTiO ₂ both induced some retarded relaxation and increased stiffening at 100 µg/mL dose. ufTiO ₂ appears to increase stiffening in a dose-dependent manner. ufEC90 induced dose-dependent acceleration of relaxation due to the carbon content of ufEC90. DEP also induced acceleration of relaxation as well as a decrease in stiffness. Phagocytosis: At 24 h, ufTiO ₂ and fTiO ₂ significantly reduced phagocytotic ability in J774A.1 but not in BD-AM. All carbonaceous particles induced significant impairment in J774A.1. All ultrafine carbon particles inhibited BD-AMs. Cell Proliferation: ufTiO ₂ significantly inhibited proliferation compared to the control and fTiO ₂ at 100 µg/mL in J774A.1. ufEC90 and ufP90 inhibited proliferation slightly with ufEC90 inducing slightly greater inhibition than ufP90. UrbD and DEP also significantly reduced proliferating. Apoptosis: All particles induced decreased viability at 100 µg/mL in both cell types. With ufTiO ₂ inducing greater apoptosis than fTiO ₂ , ufEC90 than ufP90 and ufEC90 than ufP-G. |
| Reference: Mutlu GM et al. (2006, 155994) Species: Human, Rat Cell Type: A549, Primary Alveolar Type II Epithelial Cells | PM ₁₀ (Collected by baghouse from ambient air in Dusseldorf, Germany) Particle Size: PM ₁₀ | Route: Cell Culture Dose/Concentration: 0.05, 0.5, 5. 50 µg/cm ² Time to Analysis: 24h | Na,K-ATPase Plasma Membrane Protein: PM ₁₀ induced a decrease of protein in the plasma membrane of A549 cells. Total Na,K-ATPase levels were unaffected. ROS: Pretreatment with EUK-134, superoxide dismutase and catalase mimetic, inhibited the decrease of GSH. Furthermore, it attenuated the decrease of NA,K-ATPase in A549 cells. NA, K-ATPase Activity: PM ₁₀ induced a dose-dependent decrease in ouabain-sensitive liberation of 32P from AT32P in primary rat alveolar type II cells. This effect was inhibited with pretreatment with EUK-134. |
| Reference: Nam, HR.Y. Choi, B.HR. Lee, J.Y. 2004 Species: Human Cell Type: A549 | PM _{2.5} Collected from hospital rooftop, Seoul, South Korea Particle Size: PM _{2.5} | Route: Cell Culture Dose/Concentration: 0.5, 1, 10, 25, 50 µg/cm ² Time to Analysis: 6, 24h | NFκB/IκBα: 50 µg/cm ² DEP induced IκBα degradation which peaked at 2h and recovered after 4h. Treatment with increasing amount of PM _{2.5} resulted in a dose-dependent decrease in IκBα. PM _{2.5} increased NFκB in a dose-dependent manner up to 10 µg/cm ² . NFκB induction peaked at 12h. IL-8: PM _{2.5} treatment increased protein level more than 3 fold with 100 µg/cm ² PM _{2.5} . mRNA levels also increased. iNOS Inhibitor: PM _{2.5} induced IL-8 elevation was completely blocked by iNOS inhibitor. iNOS inhibitor also negated PM _{2.5} induction of NFκB activity. Antioxidants and iNOS inhibitor reduced PM-induced IκBα degradation. |

| Reference: Okeson et al. (2004, 087961) Species: Rat Cell Type: RLE-6TN (Type II Alveolar Epithelial Cells) | Zn, V, Fe chloride as salts (valence state not reported i.e., Fe II or Fe III) Particle Size: NR | Route: Cell Culture (50000 cells/well) Dose/Concentration: 0.001, 0.01, 0.1, 1.0, 10 mM Time to Analysis: 24h | Cytotoxicity: All metals cytotoxic at concentrations greater than 0.1 mM. V is 5 times less cytotoxic than Zn, and Fe is 7 times less cytotoxic than Zn with a EC ₅₀ of 3mM and 4mM, respectively. At 10 mM of each metal, no surviving cells were present. NCS: Incubation with NCS (5 or 10 %) decreased toxicity of Zn, especially at 0.1 mM, but had no effect on Fe or V toxicity. Albumin: BSA decreased Zn toxicity at equivalent concentrations but to a lesser extent than NCS. |
| Reference: Osornio-Vargas et al. (2003, 052417) Species: Mouse Cell Line/Type: J774A.1, L929 (Mesenchymal Cells) | PM ₁₀ PM _{2.5} -N = Northern (industrial) -SE = Southeastern (lake basin dust) sites, both heavy vehicular traffic, Mexico City, Mexico Particle Size: PM ₁₀ ; PM _{2.5} | Route: Cell Culture (J774A.1: 15000 cells/cm ² ; L929: 30,000 cells/well) Dose/Concentration: 20, 40, 80 µg/cm ² Time to Analysis: 24-72h | PM Characterization: Elements similar in particle types with elements in PM ₁₀ more abundant. Northern particles contained more Co, Zn, Ni, Pb. Endotoxin: All PM samples had detectable amounts of endotoxin. PM _{2.5} -N had 22 EU/mg. PM ₁₀ -N had 30 EU/mg. PM _{2.5} -SE had 12 EU/mg. PM ₁₀ -SE had 59 EU/mg. Cytotoxicity (J774A.1): The two northern samples, PM _{2.5} and PM ₁₀ , both induced similar cytotoxic effects at 40% survival. PM ₁₀ -SE and PM _{2.5} -SE induced dose-dependent responses. In general, the northern samples had a higher cytotoxic effect than the southern samples. Apoptosis (J774A.1): Northern samples induced more apoptosis than did the southeastern samples. There was no difference between PM ₁₀ and PM _{2.5} induced apoptosis. TNF-α and IL-6 (J774A.1): TNF-α and IL-6 induced dose-dependent increases. At 80 µg/cm ² , PM ₁₀ -SE induced the most production of IL-6 followed by PM _{2.5} -SE, PM ₁₀ -N, and PM _{2.5} -N. J774A.1 Supernatant Toxicity (L929): Conditioned medium from J774A.1 pre-exposed to each PM type reduced cell viability in L929 cells. This was correlated with TNF-α level in supernatants. |
| Reference: Pei, X.H.R. Nakanishi, Y. Inoue, H.R. 2002 Species: Human Cell Type: A549 | B[a]P 1-NP: 1-nitropyrene Both purchased from Aldrich Chemical Co., MI, USA. Particle Size: NR | Route: Cell Culture Dose/Concentration: B[a]P: 10µM; 1-NP: 5 µmol Time to Analysis: 4, 8, or 24h | IL-8: IL-8 mRNA increased by B[a]P and 1-NP in a time-dependent manner with 1-NP increasing higher levels than B[a]P at half the molarity. NK-kB: 1-NP induced NF-kB DNA binding activity within 4h and maintained it for 24h. B[a]P induced similar responses. This binding was negated by treatment with a 50-fold excess of unlabeled NF-kB consensus probe. IκBα (NF-kB Inhibitor): After 3 days of treatment with the recombinant adenovirus, A549 cells expressed more than a 50-fold increase in IκBα levels, completely suppressing 1-NP induced NF-kB activation in addition to reducing IL-8 mRNA levels induced by 1-NP by 80%. |
| Reference: Penn et al. | Reference: Pozzi et al. (2005, 088610) Species: Mouse Cell Type: RAW 264.7 | PM: Collected continuously for 15 days, 8-10m from street, Sept 1999, Rome, Italy -F = Fine particulate -C = Coarse particulate CB (Degussa Huber NG90) Particle Size: PM-F: 0.4-2.5 μm ; PM-C: 2.5-10 μm ; CB: 200-250nm | Route: Cell Culture (1.3×10^5 cells/well) Dose/Concentration: 30 $\mu\text{g/mL}$; 14 $\mu\text{g/cm}^2$ 120 $\mu\text{g/mL}$; 54 $\mu\text{g/cm}^2$ Time to Analysis: 5, 24h | Cytotoxicity: For 24h, lower levels of PM-F, PM-C, and CB had no effect on cell viability. Higher levels of PM-C and CB induced a significant release of LDH. Arachidonic Acid (AA): Both fractions of PM increased AA release in a dose-dependent manner at 5h. CB increased a release only at the higher concentrations although, in terms of magnitude, the CB-induced release was much less than the ambient PM-induced release. Pretreatment with deferoxamine was not effective in decreasing AA release. TNF-α: TNF- α levels increased significantly for both concentrations and time periods for PM. PM-C at 24 h was significantly lower than at 5h for both concentrations. PM-C at 30 $\mu\text{g/mL}$ induced a much greater TNF- α release than PM-F at 5h. IL-6: PM-F significantly increased at 5h for both concentrations. Elevated IL-6 levels were exhibited at both PM-C doses at 24 h. At 5h, only the high dose elevated IL-6 levels. CB was devoid of an effect on IL-6. LPS-induced IL-6 response was similar to coarse PM at the high dose, with the response being greater at 24 h than at 5h. |
| Reference: Prophete et al. (2006, 156888) Species: Rat Cell Type: NR8383 AMs | Ambient PM _{2.5} NYC: 1st and 26 St, NYC LA: San Gabriel foothills, Claremont, CA SEA: 15th Ave S and S.Charleston, Seattle, WA V, Mn, Al, Fe levels in PM added metals to cells V: Na3VO4 Al: AlCl ₃ .6H ₂ O Mn: MnCl ₂ .4H ₂ O Fe: FeCl ₃ .6H ₂ O Particle Size: PM _{2.5} | Route: Cell Culture (2×10^5 cells/mL) Dose/Concentration: Fe(III) 16 μmol V, Mn, and Fe(III) mixtures with V or Mn in molar ratios 0.02, 0.08, 0.2 and 0.4 X Fe(III) Al and Fe(III) mixtures with Al in molar ratios 0.37, 0.75, 2, 7.5 X Fe(III) Time to Analysis: 20h | Particle Characterization: Fe and metal to F ratios based on ratios observed in PM _{2.5} from LA, SEA and NYC sites. V: Fe ratios remarkably similar among sites. Fe levels fixed at NYC level of 16 μm (highest). IRP: Coexposure with 3 metals increased IRP binding activity relative to Fe III alone, by up to 3.5 fold for Al (1.5-3 ratio), 2 fold for Mn (0.08-0.2 ratio) and 7 fold for V (0.2 ratio). IRP activity dropped at higher ratios. A drop in IRP activity at higher ratios may be result of cytotoxicity for Al, but not for V and Mn. iNOS: Al induced iNOS expression dose-dependently. There was no observed effect for Mn and V. Induction of Hypoxia-inducible Factor (HIF-1α): Only V and Al induced HIF-1 α . Activation of ERK1 and -2: V and Al induced pERK1, but only V induced pERK2. Mn had no increasing effects, but data indicated a decreasing induction. |
| Reference: Ramage and Guy (2004, 095640) Species: Human Cell Type: A549 | PM ₁₀ : Collected in Wolverhampton, UK ufCB: Ultrafine Carbon Particles (Origin not reported) Particle Size: PM ₁₀ , ufCB: < 100 nm (diameter) | Route: Cell Culture Dose/Concentration: 80 $\mu\text{g/mL}$ Time to Analysis: 0, 0.5, 3, 6, 18h | CRP: Treatment with ufCB or PM ₁₀ produced an increase in CRP expression with similar effects noted after 6h. PM ₁₀ induced greater increases than ufCB. Both the cytoplasm and nucleus contained CRP. Hsp70: PM ₁₀ and ufCB induced increased levels at all time points with ufCB inducing greater levels than PM ₁₀ . Hsp70 expression was observed in the cytoplasm and nucleus. Antioxidants of CRP and Hsp70: Coincubation of ufCB with Nacystelin and Trolox caused a small reduction in CRP and Hsp 70. |
| Reference: Rao et al. (2005, 095756) Species: Rat Strain: Sprague-Dawley Cell Type: AMs and cultured lung fibroblasts | DEP: SRM 2975 (NIST) Particle Size: 0.5 μm | Route: Cell Culture Dose/Concentration: 200 $\mu\text{g/mL}$ Time to Analysis: Measured after 4h incubation. | mRNA Expression: No change in IL-1 β or iNOS were observed. Data suggests that the lung fibroblasts is the main source of IL-6 and MCP-1 in BAL fluid because of their comparatively high message levels. Due to the extreme variability in results, the cause of an increase on co-culture with AMs and/or DEPs was not assessed. |

|--|--|--|---|
| Reference: Reibman et al. (2003, 156905) Species: Human Cell Type: HBEC, BEAS-2B | UFPM: Ultrafine PM FPM: Fine PM IPM: Intermediate PM CPM: Coarse PM CB: Carbon black All PM collected 8th floor, 26th St and 1st Ave, New York City, NY Particle Size: UFPM: < 0.18 μm ; FPM: 0.18 - 1.0 μm ; IPM: 1.0 - 3.2 μm ; CPM: > 3.2 μm | Route: Cell Culture Dose/Concentration: 11 $\mu\text{g}/\text{cm}^2$; 100 $\mu\text{g}/\text{mL}$ Time to Analysis: 6, 18h | Cytotoxicity: After treatment, cells were more than 90% viable. UFPM and FPM caused no gross alterations in cell morphology or adhesion. MIP3α/CCL20 mRNA (6h): Stimulation of mRNA released by HBEC upon exposure to UFPM appeared similar to that provided by TNF- α (5 $\mu\text{g}/\text{mL}$) and IL-1 β (10 ng/mL). MIP3β/CCL20 protein in HBEC (18h): TNF- α and IL-1 β induced a dose-dependent increase in MIP3 α /CCL20 protein (0-10 ng/mL), whereas IL-4 and IL-13 induced MIP3 α /CCL20 protein release that reached maximum levels at 1 ng/mL . No release of MIP1 α /CCL3 nor RANTES/CCL-5 was observed upon stimulation with cytokines. Secretion of MIP3α/CCL20 in response to PM (18h): All PM fractions less than 2.5 μm resulted in the release of MIP3 α /CCL20 protein in HBEC roughly equivalent amounts. CB similar in size to UF/fine PM did not result in the release of MIP3 α /CCL20, nor did LPS (0.01-1.0 $\mu\text{g}/\text{mL}$). No release of MIP1 α /CCL3 nor RANTES/CCL 5 was observed upon stimulation by PM fractions. Activation of MAPK (ERK1/2 and p38): ERK1/2 and p38 was activated by TNF- α , IL-1 β , IL-4 and IL-13 within 15 min and was sustained for at least 60 min. Erk1/2 and p38 inhibitors reduced MIP3 α /CCL20 release in BEAS-2B cells in response to cytokines. |
| Reference: Riley et al. (2003, 953237) Species: Rat Cell Type: RLE-6TN (Type II Alveolar Epithelial Cells) | Zn: ZnCl2 Cu: CuCl2 Fe: FeCl2 V: VCl4 Ni: NiCl2 Particle Size: NR | Route: Cell Culture Dose/Concentration: 0.01, 0.1, 1.0, 10 mM Time to Analysis: 2, 4, 24, 72h | Cytotoxicity (SDH): All particles were cytotoxic in a dose-dependent manner. Zn and V were cytotoxic at 0.05 mM, Cu at 0.5mM, Ni at 0.8mM and Fe at 2 mM. For Zn, cell death (LDH) had a biphasic response: a slow logslope until approx 0.1mM at which point it rapidly accelerated to a peak at 5mM with a small decline at 10mM. Most of Zn cytotoxicity was not due to apoptosis. LPS did not affect either Zn or Cu cytotoxicity. Metabolism Inhibition Time Course Response (Cu and Zn only): At high (1 mM) concentrations, Zn toxicity peaked at 36-48h followed by a 2-fold recovery by 72h. Cu showed a faster, steady decline plateauing after 36h. At low concentrations (0.1 mM), Cu showed a steady slow decline. At 48h, Zn decreased faster to max activity and returned to control by 72h. IL-6 Secretion: Zn and Cu both decreased IL-6 secretion. Decreases were very similar for both metals and concentrations when expressed as secretion per viable cell ratio except for Zn at 1.0 mM. Metal Combinations: Zn and Cu gave variable results. Zn protected against V cytotoxicity. Zn and Cu had an additive response. Zn did not affect Fe toxicity. |

|--|--|---|--|
| Reference: Riley et al. (2005, 096452) Species: Rat, Human Cell Type: RLE-6TN, NR8383 Alveolar Macrophages, A549 | Fe: FeCl ₂ Ni: NiCl ₂ Cu: CuCl ₂ V: VCl ₂ Particle Size: NR | Route: Cell Culture (5 x10 ⁴ cells/well Alveolar Cells; 1.2x10 ⁵ cells/well NR8383) Dose/Concentration: AMs: 0.02, 0.05, 0.07, 0.08 mM; RLE-6TN: 0.1, 0.2, 0.6, 1.0, 6.0 mM; A549: 0.5, 0.8, 4.4, 4.8 mM Time to Analysis: 2-48h | Relative Sensitivity of Cell Strains to Metal Chloride: NR8383 was more sensitive than RLE-6TN and A549 except for V where NR8383 and RLE-6TN were both more sensitive than A549. Relative sensitivity of Cell Strains to Metal Chloride vs Sulfate: With the exception of Cr, sulfate was generally more cytotoxic than chloride (note V valence state). A549 Cytotoxicity Time Course: Zn cytotoxicity takes 24 h to develop whereas Cu cytotoxicity develops within 2 h. LDH release for Cu, however, develops in 24h. RLE Cytotoxicity Time Course: Zn starts at 2 h and develops until 24 h. Cu develops within 2 h and continues until 24 h where it is less toxic than Zn. Both release equivalent amounts of LDH after 24 h. NR8383 Cytotoxicity Time Course: Both Zn and Cu exhibit time dependent toxicity beginning as early as 4h. LDH release maximizes at 12 h and either remains steady or declines. |
| Reference: Ritz, S.A. Wan, J. Diaz-Sanchez, D. 2007 Species: Human Cell Type: BEAS-2B, NHBEC | DX: Extract of DEP (generated from a light duty four-cylinder diesel engine 4JB1 type Isuzu Automobile) Particle Size: < 1µm (diameter) | Route: Cell Culture Dose/Concentration: 0, 20, 50, 100 µg/mL Time to Analysis: 24h | NQO1 (Sentinel Phase II Enzyme): Cells transfected with NQO1 reduced induction of IL-8 by DX exposure. Sulfurophane: Increased gene expression of phase II enzymes, particularly NQO1, was observed in both cell types. Gene expression in BEAS-2B was greater than that of NHBEC. Sulfurophane did not upregulate GSTM1 in BEAS-2B but induced a 2-fold increase in NHBEC. Pretreatment also inhibited DX-induction of IL-8 in both cell types. Cytokines: DX induced significant increase of IL-8 in both cell types at concentrations of 10 µg/mL or higher. GM-CSF and IL-8 remained unaffected in BEAS-2B. GM-CSF and IL-8 increased in NHBECs and reached statistical significance at 25 µg/mL. |
| Reference: Rosas Perez et al. (2007, 097967) Species: Mouse Cell Type: J774A.1 | PM ₁₀ Collected in Mexico City, Mexico from January-June, 2002 North: Iztacala, manufacturing industry; Center: Merced, heavy traffic; South: Ciudad Universitaria, residential Principal Component Analysis of Air Pollution Data: Group 1: S/K/Ca/Ti/Mn/Fe/Zn/Pb (43% of variance); Group 2: Cl/Cr/Ni/Cu (16%); Group 3: Endotoxins/OC/EC (14%). For all 3 sites: Averages of Group 1 is statistically different among the center, north and south sites with the central site producing the highest values. Group 2 is similar among the sites and, for Group 3, the north had a lower average than the center and south sites. Particle Size: PM ₁₀ | Route: Cell Culture (1.5x10 ⁴ cells/cm ²) Dose/Concentration: 20, 40 or 80 µg/cm ² Time to Analysis: 72h | Cytotoxicity: Responses were dose-dependent; there was no observed site interaction. Cytotoxicity seems to be a result of the following components: S/K/Ca/Ti/Mn/Fe/Zn/Pb. IL-6: Only the center site at 40 µg/cm ² induced an increase. Induction of higher IL-6 levels seems to be related to high values of S/K/Ca/Ti/Mn/Fe/Zn/Pb and endotoxins/OC/EC. TNF- α: Production was induced by all samples in a dose-dependent manner. Similar to IL-6, induction of higher TNF-α levels seems to be a result of high values of S/K/Ca/Ti/Mn/Fe/Zn/Pb and endotoxins/OC/EC. p53: Only south PM had effect. Induction of p54 seems to depend on high levels of Cl/Cr/Ni/Cu and low levels of S/K/Ca/Ti/Mn/Fe/Zn/Pb. |

| Reference: Sakamoto et al. (2007, 096282) Species: Human Age: 58-82y (Smokers) Cell Type: HBEC | PM ₁₀ : EHC-93 (Obtained from Health Canada, Canata) Particle Size: PM ₁₀ | Route: Cell Culture Dose/Concentration: 100, 300 and 500 µg/mL Time to Analysis: Calcium responses: up to 60min; cytokines: 6 or 24h | Intracellular [Ca²⁺]: [Ca] concentration slowly increased, elevating after 10 and 30 min for 500 and 300 mg/mL, respectively. The response plateaued at 35 min for 500 µg/mL. Extracellular [Ca²⁺]: Starting at 20 min, the removal of extracellular Ca decreased the PM ₁₀ response significantly. Calcium channel blocker (10µM or 1mM) LaCl3 and (5mM) NiCl2 significantly blocked the PM-induced intracellular Ca. LaCl2 administration (1mM) inhibited the PM-induced Ca ²⁺ response in a dose-dependent manner. Mode of Action: Intracellular Ca induced by ATP declined more slowly in the cells exposed by PM ₁₀ . This indicates that PM ₁₀ blocks Ca clearance via the calcium pumps. Cytokines: PM ₁₀ induced a dose-dependent increase in cytokine mRNA levels and cytokines IL-1β, LIF, IL-8 and GM-CSF. Cytokine expression was unaffected by the reduction of extracellular Ca ²⁺ . Preincubation with the calcium chelator reduced responses for IL-1β and IL-8 but not LIF or GM-CSF. |
| Reference: Salnikow et al. (2004, 087469) Species: Human Cell Line: 1HAEo- | FeSO ₄ FeCl ₃ NiSO ₄ Particle Size: NR | Route: Cell Culture Dose/Concentration: 0.25mM Fe exposures also contained 60 µg/mL apotransferrin Time to Analysis: 24h | Cytotoxicity: Both Fe had no effect. NiCl ₂ caused marginal cytotoxicity (75%). Hypoxic Stress: At 20h, NiSO ₄ (at concentrations of 0.25 or 0.5mM) induced NDRG-1/Cap43 protein production indicating hypoxic stress. DFX and DMOG induced a similar effect. IL-8: NiSO ₄ induced IL-8 time-dependently for up to 48h. At 48h, the increase was 6+ fold. Coexposure (Ni + Fe) on Fe uptake: Fe III uptake was greater than Fe II uptake. NiSO ₄ had no effect. Ni uptake was greater than Fe uptake but was decreased by coexposure to Fe. Coexposure also did not effect hypoxic stress. Coexposure with Fe did reduce Ni-induced IL-8 production. |
| Reference: Salonen et al. 2004 (2004, 187053) Species: Mouse Cell Type: RAW 264.7 | PM ₁₀ (urban traffic) Finland (filter sonicated in water and methanol, extracted with methanol) Pooled as winter (W) spring I (SI) or spring II (SII) based on component/time considerations HVLI slit impactor Particle Size: PM ₁₀ : 0.12-10nm | Route: (2x10 ⁶ cells/well) Dose/Concentration: 15,50, 150,500, 1000 µg/mL Time to Analysis: 0, 24h | Air quality parameters: Winter and spring I did not differ. SII much lower PM _{2.5} PM ₁₀ W = 18.6 ± 10.1; SI = 28.0 ± 5.5; SII = 20.3 ± 2.4 µg/m ³ Metal data equivocal as well as highly variable resuspension rates Total PAHs: W = 303; SI = 233; SII = 204 ng/mg PM ₁₀ (ppb) Inflammation (IL-6, TNF, NO): A dose-dependent increase was observed for TNF, IL-6 and NO except for SI. The IL-6 levels, of those particles exposed to SI, decreased at 1000 µg/mL. TNF, IL-6: SI = SII > W > control. NO production: W > SI > SII Cell Viability: W = SI = SII toxic at 500 and 1000 µg/mL Watersoluble vs Insoluble: TNF and IL-6 were nearly entirely the result of insoluble components of PM ₁₀ . Cytotoxicity was driven by both soluble and insoluble components. Metal Chelation: The addition of metal chelators did not modify IL-6, TNF or cytotoxicity LPS inhibitor: Treatment with the LPS inhibitor eliminated the IL-6 response and, perhaps, slightly reduced the TNF response but not cytotoxicity Hydroxy radicals: A dose-dependent induction of hydroxy radicals and induction of hydroxy radical lesions (at 500 and 1000 µg/m ³) in the calf thymus DNA were observed. |

|--|--|--|---|
| Reference: Samet et al. (2003, 113782) Species: Human Cell Type: A431 (Epidermoid Cells) | As: NaAsO ₃ V: VOSO ₄ Zn: ZnSO ₄ (obtained from Sigma, St. Louis, MO) Particle Size: NR | Route: Cell Culture Dose/Concentration: 500 µM Time to Analysis: 20, 30 or 90min | EGFR Dimerization: Zn, V or As did not induce EGFR dimerization in a cell free system i.e., no direct crosslinking. Zn did not induce dimerization in whole cells either. Phosphorylation of EGFR: Zn induced phosphorylation at 3 sites similar to EGF. As and V had no effect. EGFR Kinase Inhibitor: While EGF action was blocked, Zn continued to induce phosphorylation and was independent of EGFR kinase activity. c-Src: Blocking of c-Src tyrosine kinase (transactivator of phosphorylation) negated all Zn-induced phosphorylation but only had a slight effect on EGF stimulated cells. ERK1/2 Phosphorylation: Zn increased levels of ERK1/2. Pretreatment with EGFR kinase inhibitor reduced both Zn and EGF effect. This effect was not blocked by the c-Src blocker. |
| Reference: Santini et al. (2004, 087879) Species: Mouse Cell Type: RAW 264.7 | DEP: PM _{2.5} Collected adjacent to moderate traffic in Rome, Italy Particle Size: PM _{2.5} | Route: Cell Culture (2.5 X 10 ⁵ cells/mL) Dose/Concentration: 0.01, 0.1, 1.0 µg/mL Time to Analysis: 24h | 500 MHz results (no 1 µg/mL): DEP induced a dose-dependent increase in choline compounds, α- and βgamma- glutamine/glutamate (0.01 > 0.1 µg/mL), lactate, and CH ₂ , CH ₃ moieties of fatty acids. DEP decreased inositol and (phosphoreatinine). 700 MHz results (no 1 µg/mL): DEP induced similar results, except α-, βgamma-glutamine were dose-dependent. Inositol showed no effect. Taurine slightly increased. Results were confirmed after eliminating biological interferences via perchloric acid. Growth Curves/Cell Cycle Analyses/Cell Morphology: DEP had no effect. Cytokines: IL-6 levels increased at 0.1 and 1 µg/mL. TNF-α was unaffected. |
| Reference: Saxena et al. (2003, 096986) Species: Mouse Cell Type: RAW 264.7 | DEP: SRM 1650 CO: Crude Organic Extract of DEP Fractionated into asphaltene (pentane/hexane), saturated hydrocarbon, less polar (aromatic) hydrocarbon, more polar (aromatic) hydrocarbon, resins, residual (resins) Particle Size: NR | Route: Cell Culture (2.5 X 10 ⁴ cells/mL) Dose/Concentration: DEP, CO 5, 10, 15, 20, 25 µg/mL IFNγ 10 ng/mL LPS 1 mg/mL Time to Analysis: 1-3d | Cytotoxicity: No cytotoxic effects were observed. NO: DEP alone induced NO in a dose-dependent manner which peaked after 1d and plateaued for days 2 and 3. IFNγ + DEP showed dose- and time-dependency. LPS + DEP showed no effect at 1d, but dose-dependently reduced NO production on day 2 and 3. Addition of BC G eliminated the effect of DEP at 2d but showed a dose-dependent decrease at 3d. Effectiveness of Particulate Components: The carbonaceous core of DEP did not affect BC G-stimulated NO production. CO significantly inhibited BC G-stimulated NO production. Study indicated that the extract of aromatic hydrocarbons and resins caused an inhibitory effect in a dose-dependent manner. |

| Reference: Seagrave et al. (2007, 097549) Species: Human Gender: Male (3 donors) Age: 16, 23yrs Cell Type: Differentiated A549 | DE: Generated by DE 5500 watt generator using #2 certification oil performed under 5000w load. Emissions diluted to 3 mg/m ³ total particulate matter. Particle Size: 0.14 - 0.5 μ m | Route: Air Liquid Interface Dose/Concentration: 8.33 mL/min/well Time to Analysis: 3h; 1 or 21h post-exposure | Particle Deposition: 140 and 500 nm microspheres demonstrated uniform deposition of approx. 10% Transepithelial Electric Resistance: No effect of DE; rather, more effect was observed from air controls Macromolecular permeability: DE caused an increase 1-h but returned to control at 21h. LDH/Cytotoxicity: DE had a highly variable(donor specific) effect at 1-h and returned to control levels at 21h Mitochondrial activity (WST): DE reduced activity at 1-h and possibly increased activity at 21h (high donor-to-donor variability) MucusLike Substance Excretion: There was high donor to donor variability; no overall effects were observed. Alkaline Phosphatase (AP): DE decreased at 1-h and perhaps increased at 21h Glutathione: DE caused a large decrease at 1-h but returned to normal at 21h. HO-1: After DE exposure, levels increased but were still lower than air exposed controls Cytokines: No differences for IL- 8 or 12, TNF α , GM-CSF, IL-1 α , or IFN γ were observed. IL-4 and 6 were decreased upon DE exposure. |
| Reference: Seagrave et al. (2004, 087470) Species: Human Cell Type: A549 | DPM: SRM2975 (NIST) DPM-O: DPM organic extract (acetone/DCM) CB: Carbon Black (Elftex-12, Cabot) Particle Size: CB: 37nm; Stokes diameter 198nm | Route: Cell Culture (1x10 ⁵ cells/well) Dose/Concentration: 0.03 - 1,000 μ g/cm ² Time to Analysis: 0, 18h | IL-8 release: DPM increased semi dose-dependently (perhaps steady based on error range) up to 1 μ g/cm ² after which IL-8 declined dose dependently to zero (control = 100%) at 300 and 1000 μ g/cm ² . LDH release was steady which indicates no cytotoxicity. DPM interaction with IL-8: DPM depletes IL-8 from solution in a dose-dependent manner (cellfree). BSA preincubation reduced the slope of the dose response but not the final result. CB has no effect. DPM-O residuals act identical to DPM. Increasing NaCl concentrations reduced DPMs depletion of IL-8 Neutrophil responses: DPM and bound IL-8 together caused a marked aggregation of cells resulting in spindle shapes. DEM or IL-8 alone did not cause this aggregation although DEP did recruit neutrophils |

| Reference: Seagrave et al. (2003, 054979) Species: Human, Rat Cell Line: F344/Crl BR (mouse) Age: 11 wks (mouse) Weight: 250g Cell Type: A549, AMs | PM filter collection Collected from diesel or gasoline powered vehicles as follows: BG: Black Smoke Gasoline G30: Normal Emitter gasoline (30F) G: Normal emitter gasoline (72F) HD: High Emitter Diesel D30: current technology diesel (30F) D: current technology diesel (72F) WG: White Smoke Gasoline Particle Size: NR | Route: Cell Culture (1x10 ⁵ cells/well) Dose/Concentration: 0.03 – 10,000 µg/cm ² Time to Analysis: 16-18h | Cytotoxicity: LDH activity increased in A549 cells. The types of pollutants that are most toxic, in decreasing order of cytotoxicity, are the following: BG, G30, and G which are significantly different from HD, D30, D, WG which are also significantly different from DS. LDH activity also increased in rat macrophages. G, G30, and BG were the most toxic. HD and D30 were intermediately toxic and D, WG, and DS were the least toxic. In both cell types, gasoline was more cytotoxic than diesel. Cytokines: All particle types except DS increased IL-8 levels in A549 though not all increases were statistically significant. Also, many particle samples at high concentrations produced an apparent suppression of IL-8 release. Alkaline Phosphatase: G30 and G were more potent than the other particle samples in A549. WG and D30 induced no significant effects. For A549 cells, activity increased at low concentrations and was suppressed at higher concentrations. Macrophage Peroxide Production: In rat AMs, peroxide production was often the highest at the lowest concentrations and the lowest production caused by the highest concentrations. D30 followed this trend and induced the highest production as well as the greatest suppression. Using two different statistical methods, D30 > 6 others which in turn > DS. Using the second method D30 and D > all other 6. Order of potency between two methods completely different. Authors noted that in vitro potency quite different from in vivo potency (previous paper). |
| Reference: Seaton. et al. 2005 Species: Human Cell Type: A549 | PM _{2.5} from London PM ₁₀ from Manchester (positive control) PM from Holland Park, Hampstead and Oxford Circus stations (HP, HR and OC) PM _{2.5} monitoring Holland Park, Hampstead and Oxford Circus PM had a median diameter of 0.4 µm. 80% of the particles had a diameter less than 1 µm. Particle Size: PM _{2.5} , PM ₁₀ , Holland Park, Hampstead and Oxford Circus PM had a median diameter of 0.4 µm. 80% of the particles had a diameter less than 1 µm. | Route: Cell Culture Dose/Concentration: 1 - 100 µg/mL Time to Analysis: Cytotoxicity: 24h; IL-8: 8h; Generation of hydroxy radicals: 8h | Cytotoxicity: Dust from all three tunnels (Holland Park, Hampstead and Oxford Circus) were able to cause cell death (LDH). The release of LDH indicated a dose-dependent relationship. The highest dose of Holland Park PM induced the ~ 17% release of LDH, Hampstead triggered ~ 13% and Oxford Circus ~ 3% (no different than control). PM ₁₀ from Manchester caused a 7% LDH release at the highest dose. The negative control (TiO ₂) caused no response (2% release at highest dose). IL-8: All three tunnel PMs induced a dose-dependent release of IL-8. At the highest dose, all three tunnel dusts induced IL-8 stimulation more so than the control site PM _{2.5} . HP induced a 3 fold increase. Also, the highest TiO ₂ concentration caused the least IL-8 stimulation. Hydroxy Radical Generation/ DNA Plasmid assay: The plasmid assay indicated that the tunnel dusts induce more free radical activity than the Manchester PM ₁₀ and TiO ₂ . HP nearly doubled the percentage of DNA damage with intermediate results for HR and OC. Results for PM ₁₀ , TiO ₂ and control were identical |

|---|--|--|--|
| Reference: Singal et al. 2005 Species: Human, Mouse Cell Type/Line: A549Luc1 lung adenocarcinoma epithelial cell line (human), MLE15Luc1 and MLE15Luc2 (mouse) All cells contain human cytokine IL-8 controlling firefly luciferase | AE2: Aerosil 200, amorphous silica (Degussa) CI: Carbon iron particles (25 % Fe) Particle Size: AE2: 12nm surface area ~ 200 ± 25 m ² /g; CI: ~ 40nm | Route: Cell Culture (5x10 ⁵ cells/well) Dose/Concentration: 18 µg/mL, 36 µg/mL, 72 µg/mL all in 1mL /well Time to Analysis: 24h | Luc activity: Luciferase enzyme activity is significantly less in MLE15Luc2 cells than in MLE15Luc1 cells. For both cells, luciferase activity is time- and dose-dependent peaking at 4-8 hours. Aerosil 200: AE2 induced dose- and time-dependent Luc response which peaked at 3 h and decreased thereafter in a similar way as TNF. Contrary to TNF, AE2 induced much cytotoxicity starting at 6h. Effect of proteasomal inhibitors (MG-132): Inhibitor reduced AE2 Luc activity to near control levels. Similarly, LDH-cytotoxicity was halved A549 human cell response: AE2 acted similarly to the MLE response. CI particles showed slightly less activity without peaks. AE2 increased cytotoxicity after 12 h, whereas CI had no effect. Contrary to MLE mouse, MG_132 did not affect Luc activity but PD98059 (selective noncompetitive inhibitor of the MAP pathway) and SN50 (NF-κB inhibitor) reduced AE 2 and CI-induced activity. |
| Reference: Song et al. (2008, 156093) Species: Rat Cell Type: RAW 264.7 | DEP collected from a 4JB1-type, light-duty (2740 cc), four-cylinder diesel engine operated using standard diesel fuel at speeds of 1500 rpm under a load of 10 torque. Particle Size: 0.4 µm (mean diameter) | Route: Cell Culture (5 X 10 ⁵ cells seeded on a 24-well plate) Dose/Concentration: 50 µg/mL Time to Analysis: Nitrate production: 72h. | Nitrite Production: 50 µg/mL of DEP induced production when compared to the control. Over the 72-h period, a general trend was not observed, but maximal induction of nitrite occurred at 4 h after stimulation. |
| Reference: Steerenberg et al. (2006, 088249) Species: Rat, Human Cell Line: CrI/WKY (rat) Cell Type: AMs (rat), alveolar epithelium cells (rat), A549 | PMC: PM Coarse PMF: PM fine Ambient air samples collected from Rome, Italy; Oslo, Norway; Lodz, Poland; Amsterdam, the Netherlands; De Zilk, the Netherlands. Particle Size: PMC: 2.35 - 8.5 µm; PMF: 0.12 - 2.35 µm | Route: Cell Culture Dose/Concentration: NR Time to Analysis: 20h | Crustal material (metals and endotoxin but not Ti, As, Cd, Zn, V, Ni, Se) were positively associated with on vitro rat macrophage IL-6 and TNFα and in vitro Type 2 (rat alveolar) MP-2 and IL-6. Sea spray (Na and Cl) was also correlated with Macrophage IL-6 |
| Reference: Tal et al. (2006, 108588) Species: Human Cell Type: HAEC | 100 mM Zn(II) or V(IV) stock solutions (NOS) Particle Size: NR | Route: Cell Culture Dose/Concentration: 500 µmol Time to Analysis: 5, 20min | Zn-mediated EGFR phosphorylation: EGFR kinase activity was required but not EGFR ligand binding. EGFR Kinase inhibition reduced Zn mediated EGFR activation. (authors NOTE: complete reverse of results in B82L and A431 cells). Src Kinase is not required. Zn inhibiting Src kinase was nearly total after 20 min. EGFR-specific protein tyrase phosphatase (PTP): Zn inhibited PTPs, similar to V(IV) resulting in a decrease of exogenous EGFR dephosphorylation |
| Reference: Tamaoki et al. (2004, 157040) Species: Human Cell Type: HBEC | UFCB: Ultrafine Carbon Black - (Tokai Carbon, Japan) FCB: Fine Carbon Black (Tokai Carbon, Japan) Particle Size: UFCB: 11 ± 0.5 nm (mean diameter) FCB: 250 ± 16nm (mean diameter) | Route: Cell Culture (10 ⁴ cells/well) Dose/Concentration: 6.1, 12.3, 18.4, 24.5, 30.7 µg/cm ² Time to Analysis: Up to 72h | DNA synthesis/ Protein synthesis: Synthesis increased by UFCB (30.7) for up to 72 h and flattened after 48 h. FCB had no effect. UFCB also showed a dose-dependent response beginning at 12.3 µg.cm ² up to 24.5 whereafter the response plateaued. The addition of Cu/Zn Super oxide dismutase (SOD) or a NADPH oxidase inhibitor completely inhibited the UFCB effects. Similarly, two different EGFR tyrosine kinase inhibitors, and a Me inhibitor all reduced UFCB response to control levels. ERK activation: UFCB caused phosphorylation of ERK beginning at 2 min, peaking at 5 min and decreasing at 10 min. ERK activation was inhibited by EGFR tyrosine kinase inhibitor Cu/Zn SOD and neutralizing body for HB-EGF but not by PDGF-R kinase inhibitor. HB (polyclonal heparin binding)-EGF release: UFCB induced rapid cell surface loss with recovery after 20 min and nearly full recovery at 360 min. Metalloproteinase inhibitor and Cu/Zn SOD both prevented HB-EGF release. |

| Reference: Tao and Kobzik (2002, 157044) Species: Rat Cell Type: RLE-6TN (Alveolar Type II Epithelial Cells), Fetal Lung Fibroblasts (RFL), AMs | UAP: Urban Air Particles = SRM 1649 TiO ₂ : Titanium dioxide SiO ₂ ROFA Particle Size: TiO ₂ : ~ 1µm; SiO ₂ : ~ 1µm; ROFA: NR | Route: Cell Culture (1x10E5 cells AM 1.4x10E5 cells RLE/RFL) Dose/Concentration: 1-50 µg/mL Time to Analysis: 24h | Cytokines: TNF-α and MIP-2 in RLE was unaffected by any particle samples. TNF-α and MIP-2 in AM significantly increased with 25 µg/mL UAP. TNF-α and MIP-2 in the co-culture of AM + RLE increased with each particle. The order of particles in decreasing order are as follows: SiO ₂ at 25µg/mL, UAP at 12.5 µg/mL, ROFA at 25 µg/mL, and TiO ₂ at 50 µg/mL. Except for SiO ₂ , the blocking of effects caused by LPS absorbed on the particles did not affect the cytokine response. For SiO ₂ , the response was reduced but still above the control. Co-culture: Physically separating AM and RLE cells and adding PM completely negated the co-culture's response to PMs. This indicates that cell to cell contact is required for co-culture potentiation of PM effects. Inhibitors: Various inhibitors of cell adhesion molecules (heparin, β -1, 2 or 3 integrin) had no effect on UAP-induced cytokine release. |

IL-6 secretion in BEAS-2 B cells: Nano and micro sizes of the same metal showed no differences in response (high experiment to experiment variability). In general, the soil-derived dusts (JE, DD, MNC) were more potent than the metal and ceramic oxide particles. In KGM media, BEAS-2B cells are more responsive to vanadium and other soluble metals and less responsive to LPS, but this relationship is reversed in LHC-9 media. IL-8 secretion in BEAS/LHC vs NHBE in BEGM cells: Levels were much higher in NHBE cells than BEAS-2B cells. For BEAS-2B, the nano size Si and both sizes of Ni induced levels statistically greater than the control. For NHBE, only Si and Ni (for both sizes) were statistically greater than control. IL-6 in NHBE: The nano and micro sized particles of Al, Ce, Fe and nano sized Si all induced statistically significant increases. Control levels of IL-6 were much higher in NHBE cells than in BEAS-2B cells. Secretion induced by pure oxide particles was small for both the mid and high concentration levels (5.3 and 53 µg/cm ²). BSA/ Bovine serum addition effect: In a fixed solution nano-Ni, nano-Ti and KLN all reduced the measured IL-6 by 60+ percent. Addition of BSA or bovine serum dose dependently reduced the action of the particles to near control levels. PM effects (without added protein) on IL-6 in solution: Increasing metal concentration did not affect a fixed IL-6 concentration until the 100 or 316 µg/mL levels. |

Vanadium, at the highest concentration, induced less than 50% of control viability whereas kaolin, also at the highest concentration, induced cell death.</p> <p>Cytokine IL-6: BEAS-2B E or U in LHC-9 showed a response to S and L. BEAS-2B (U) was in LHC-9 medium with added serum (FBS). This resulted in a doubling of response coupled with at least an 8 fold increase in control levels. BEAS-2B (E) showed response for S and V but not L. A549 showed response to S and K. RAW 264.7 and Rat macrophages showed responses to S (very low) and L. In general, the IL-6 responses in A549 and RAW 264.7 were similar and significantly lower than the responses in rat macrophages or BEAS-2B.</p> <p>Effect of culture media composition (BEAS-2B): Varying ratios of LHC-9 and KGM media resulted in a near 10 fold increase in control rate once LHC was 33% or more of the media. Upon Soil Dust (NOS) exposure IL-6 increased linearly with % LHC-9 in culture/exposure media. Addition of calf serum (0.1-10 %) raised control IL-6 levels at least 40 fold. At a steady PM concentration, the addition of serum resulted in a log-linear increase in IL-6 release which blocked any PM effect.</p> <p>Reversibility of media effect: Changing media with every passage showed that media effects do not persist once media are changed.</p> <p>Culture Well Size: Going from a 6 well to 96 well plate (decreasing well size) increased IL-6 control values about ten fold, while the positive control (TNF) response increased 3 fold. Hence the sensitivity of the test (i.e., positive/control response) declined from 11 fold to 3 fold with increasing well number / decreasing well size. Because cell seeding density and the like were held constant, these changes suggest that edge effects are the cause of the IL-6 changes.</p> |

| Reference: Veranth et al. (2004, 087480) Species: Human Cell Type: BEAS-2B Veranth et al. 2004 | PM _{2.5} enriched soil samples DD: desert dust, unpaved road, Utah WM: West Mesa, sandy grazing site, NM R40: Range 40 gravel soil, TX UN: Uinta, sandy soil, UT Particle Size: 0.4 - 3 μ m | Route: Cell Culture (20,000/cm ²) Dose/Concentration: 10, 20, 40, 80, 160 μ g/cm ² Time to Analysis: 24h | Elemental Analysis of PM's: Major differences UN generally lower in major minerals but high Fe content and high EC. High Mn. Low Pb and Zn Cytotoxicity: UN and WM were the most cytotoxic at all dose levels, followed by R40 and DD. All particles showed a dose-dependent cytotoxic response. IL-6 Release: DD and R40 (up to the 160 μ g/cm ²) showed dose-dependent responses and induced an 8-fold increase at the highest concentration levels. WM peaked at 40 μ g/cm ² and UN induced similar responses above 10 μ g/cm ² . IL-8 release: DD induced a dose-dependent response. WM peaked at 10 μ g/cm ² . Release induced by DD and WM seemed to be limited by toxicity. There was no treatment with R40. TNF-α: DD, WM and UN induced release was not detected at the 40 or 80 μ g/cm ² concentrations. LPS: LPS was the primary factor in inducing IL-6 release when exposed to LPS-containing mixtures. LPS alone induced lesser responses than treatment to the environmental dust particles. TiLPS induced a less than two-fold increase in IL-6 versus the over seven-fold increase induced by soil dust positive control. LPS treatments were less cytotoxic than DD. Limited IL-6 and IL-8 responses were observed at 2000 EU/mL compared with DD at 80 μ g/cm ² Endotoxin: Inverse relationship between endotoxin content and IL-6 release was observed. Viability vs Physical Modification of Dust Sample (no UN): Only leaching in a variety of water based vehicles increased viability minimally (generally < 25 %). Heat treatment (150-, 300, 550F) and methanol extraction had no effect IL-6 release vs Physical Modification of Dust Sample (no UN): One hour thermal treatment at 150 \square F had no effect on IL-6 response. All other treatments reduced IL-6 release (heat 350 \square , 500 \square and extractions). |

(2005, 087891) Species: Human Cell Type: U937 (ATCC) monocytes (macrophage differentiation) | UDP: SRM 1649 (NIST) UDP-OE: DCM extract of SRM-1649, 0.45 μ m filter sUDP: stripped particles UDP DEP: SRM 2975 (NIST) DEP-OE: DCM extract of SRM-2975, 0.45 μ m filter sDEP: stripped particles DEP CB95: Carbon Black (Degussa) Particle Size: UDP, DEP: NR; CB95: 95nm | Route: Cell Culture (2×10^5 - 2×10^6 cells/mL) Dose/Concentration: DEP, UDP: 2.5, 10 or 40 μ g/cm ² (eq to 12.5, 40, 200 μ g/mL) DEP-OE, UDP-OE: 10 μ g/cm ² (particle equivalent) Time to Analysis: 24h | Effect on mRNA expression (COX-2, TNFα, IL-6, IL-8, C/EBPβ, CRP, CYP1a1): All DEP and UDP induced dose-dependent increases. IL-6 tended to plateau at 10 μ g/cm ² . Generally, with the exception of COX-2, UDP effects on genes were stronger than DEP. Cytotoxicity: Both DEP and UDP were cytotoxic at 40 μ g/cm ² Fractionation and mRNA expression: For COX-2, TNF α , IL-8 mRNA fractions were much more active than parent particles and consequently stripped particles were much less active than parent particles. CB95 had no effect. The reverse effect occurred for IL-6 and CRP mRNA expression. The particles that induced mRNA expression in decreasing order are: sUDP, UDP, UDP-OE. Inhibition of mRNA expression: CRP: pretreatment with IgG and wortmannin (Fc γ receptor binding and ingestion dependent inhibitors resp) blocked the effects of DEP, UDP and sDEP and sUDP. Luteolin (AhR inhibitor) had no effect. COX-2: Only luteolin inhibited COX-2 expression for DEP, DEP-OE, UDP, and UDP-OE. CYP1a1: Luteolin also inhibited OE-DEP and OE-DUP effects (only those two particles tested). Cholesterol accumulation: DEP, UDP and UDP-OE and DEP-OE at 10 μ g/cm ² all increased cholesterol accumulation by at least 2 fold |
| Reference: Wang et al. (2003, 157106) Species: Rat Cell Type: Lung Myofibroblasts | V ₂ O ₅ : (Aldrich Chemical Co., Wisconsin) Particle Size: NR | Route: Cell Culture (1×10^5 cells/100 mm dish; 3.2×10^4 cells/cm ²) Dose/Concentration: 400 μ m Time to Analysis: 0.5, 1, 4, 24h | H₂O₂ drives STAT-1 activation: Pretreatment with NAC or catalase reduced V ₂ O ₅ -induced STAT activation by more than 90% and completely abolished H ₂ O ₂ -induced STAT activation. Within 5 min of V ₂ O ₅ treatment, H ₂ O ₂ was significantly decreased in the supernatants of cultured myofibroblasts and suppression of H ₂ O ₂ levels continued for up to 24h post V ₂ O ₅ treatment. This supports the findings that myofibroblast-generated H ₂ O ₂ is required for V ₂ O ₅ -induced STAT activation. Temporal STAT-1 activation: H ₂ O ₂ induced rapid activation within minutes whereas activation by V ₂ O ₅ occurred more slowly (beginning 8h post treatment). p38, ERK, EGFR: p38 and EGFR are required for H ₂ O ₂ - or V ₂ O ₅ -induced STAT-1 activation whereas ERK is not required |
| Reference: Whitekus et al. (2002, 157142) Species: Mouse Cell Line: RAW 264.7 | DEP (light-duty, four-cylinder engine- 4JB1 type, Isuzu Automobile, Japan; standard diesel fuel) (extracts) Particle Size: NR | Route: Cell Culture Dose/Concentration: 50 μ g/mL Time to Analysis: DEP extracts suspended in methanol and sonicated 20min. Centrifuged 10min. Dried DEP resuspended and stored -20°C. Cell cultures maintained 37 °C. Exposed to antioxidants 5h. HO-1 western blot, determination of cellular GSH:GSSG ratios, carbonyl protein content, lipid hydroperoxides performed. | DEP significantly reduced the GSH:GSSG ratio. This effect was prevented by adding thiol antioxidants NAC or BUC. DEP increased lipid peroxide levels, but the addition of all antioxidants decreased these levels. DEP increased carbonyl groups. NAC, BUC, and luteolin reduced HO-1 expression. |

| Reference: Wilson et al. (2007, 097268) Species: Mouse Cell Type: J774 | CB: Carbon Black, Printex 90 (Degussa) FeCl ₃ ZnCl ₂ Particle Size: CB: 14 nm | Route: Cell Culture (4 X10 ⁵ cells/mL at 1mL/well) Dose/Concentration: CB 1.9 -31 µg/mL; FeCl ₃ , ZnCl ₂ 0.01 - 100 µmo Time to Analysis: 4h | ROS production in cells: CB alone increased ROS. Coexposure with ZnCl ₂ did not affect ROS. ROS production - cell free: CB induced a significant increase in ROS. ZnCl ₂ had no effect. Coexposure CB/Zn also had no effect. TNFα production (Fe -Zn 0.01-100 µmol): Coexposure of CB over a range of metals gave no change over CB alone for Fe. For Zn, only at the concentration of 100 µmol was there a small interaction between Zn and CB. Similar results were seen at metal concentrations between 20 -100 µmol. Synergism was observed between Zn and CB and no observed effect of Fe. Macrophage cytoskeleton: CB resulted in black vacuoles. Co-treatment of cells with Zn and CB increased the severity of Zn effects. Fe exhibited no synergism. Apoptosis /necrosis: No synergism of CB with either Fe or Zn Phagocytosis: Only at 31 µmol CB and 50 µmol Zn did a synergistic effect occur; it resulted in a 4-fold reduction |
| Reference: Wottrich et al. (2004, 094518) Species: Human Cell Type: A549, THP-1, Mono Mac 6 | Fe: hematite α-Fe ₂ O ₃ Si60: silicasol (SiO ₂ , amorphous silica) Si100: silicasol Q: crystalline quartz DQ12 Particle Size: Fe: 50 - 90nm; Si60: 60nm; Si100: 80 -110 nm; Q < 5 µm | Route: Cell Culture (2 X10 ⁴ cells/well. Co-culture: 2 X10 ⁴ A549 and 2 X10 ³ Macrophages) Dose/Concentration: A549 light microscopy hematite 100µg/mL (23 µg/cm ²) TEM hematite 50 µg/mL (16 µg/cm ²) Cytotoxicity 10, 50, 100 and 200 µg/mL (6.1, 30, 61 and 121 µg/cm ²) Cytokines 50 and 200 µg/mL Time to Analysis: 24 h | Particle Uptake: Hematite agglomeration was observed in all 3 cell lines. TEM confirmed cytosol aggregates as well as single particles, which includes particles transported intracellularly to basolateral membrane of epithelial cells. Cytotoxicity: LDH increased significantly in A549. In decreasing order, Q , Fe, S60, and S100 (which exhibited levels similar to controls) all induced cytotoxicity. THP-1 cells appeared the most sensitive with Q, Fe, S60, S100, control inducing cytotoxicity in decreasing order. Mono Mac 6 cells were the least sensitive with Fe, S60, Q, S100. Cytokines: IL-6 and IL-8 released from A549 cells upon exposure to all particles. No response was observed in Mono Mac 6 or in THP-1 cells. Co-cultures: Mix of A549 with either Mono Mac 6 or THP-1 led to a large (ten fold) increase in response to particles. Ten fold increases were observed in IL-6 and IL-8 levels with the Mono Mac 6 co-culture and the THP-1 co-culture, respectively. |

EGFR-c'958 lacks all 5 tyrosine autophosphorylation sites. EGFR-K721M lacks tyrosine kinase (ATP binding). EGFR-Y845F lacks Src autophosphorylation (Tyr 845) and, instead, has a receptor at Tyr 845 that is phosphorylated by nonreceptor Tyrosine kinase Src.</p> <p>Zn Induced Ras (MAPK signaling protein): No effect was observed in B82L-par cells. Zn had an effect in -wt, -c'958, and -K721M which confirms the need for EGFR. This indicates that neither tyrosine kinase nor autophosphorylation sites were required for Zn effects. No observed increase for Y845F indicated that EGFR tyrosine 845 (phosphorylated by c-Src) is required for Zn effects. However, it was not required for EGF effects.</p> <p>Src Kinase requirement: Using a Src blocker drastically reduced Zn effect but not the EGF effect. Src activation occurred independent of EGFR Tyr-845.</p> <p>Zn induced association of EGFR with Src: Zn induced a physical association in all 4 mutants; EGF did not.</p> <p>Zn induced phosphorylation of EGFR at Tyr-845: Zn induced phosphorylation of EGFR at Tyr-845 in B82L-wt, -c'958 and -K721M. EGF exhibited similar effects. Src blockers significantly reduced phosphorylation induced by Zn but not for EGF. Neither Zn or EGF induced phosphorylation in B82L-Y845F cells.</p> |
| Reference: Wu, W. Wang, X. Zhang, W. 2003 Species: Human Cell Type: BEAS-2B | Zinc Ion: Zn ²⁺ Particle Size: NR | Route: Cell Culture Dose/Concentration: 10, 25, 50 μ mol Time to Analysis: 0-8h | <p>Cytotoxicity: Exposure to 50 μmol Zn²⁺ for 8h did not result in significant alterations in cell viability.</p> <p>PTEN Protein Levels: 50 μmol Zn²⁺ for 4 and 8h significantly decreased levels in a dose-dependent manner. Exposure to 50 μM vanadyl sulfate (tyrosine phosphatase inhibitor) had minimal effects on PTEN. 100 ng/mL of non-specified EGF receptor ligand for 1-8h did not exhibit any significant effects on PTEN levels.</p> <p>P13K/Akt: Zinc induced Akt activation in a dose- and time- dependent fashion. Active Akt levels were the highest at 1 h post exposure to Zn²⁺, corresponding with the time period when there was a minimal effect on PTEN protein level. When treated with LY294002 (inhibitor of P13K activity), Akt phosphorylation was significantly inhibited.</p> <p>PTEN mRNA Levels: Decreased PTEN mRNA expression was observed in cells exposed to 50 μmol Zn²⁺ for 8h whereas PTEN protein levels declined as early as 4h.</p> <p>Proteasome-mediated PTEN Degradation: Use of MG132 (proteasome inhibitor) had no significant effect on Zn²⁺ induced PTEN mRNA expression. Therefore mRNA expression may not play a critical role in PTEN protein reduction. Instead data suggested that 26 S proteasome played a vital role in Zn²⁺ induced PTEN degradation. PI3K inhibitor blocked Zn-induced PTEN degradation, but failed to prevent significant Zn-induced down-regulation of PTEN mRNA.</p> |

| Reference: Wu et al. (2004, 096949) Species: Human Cell Type: NHBE | Zinc Ion: Zn^{2+} Particle Size: NR | Route: Cell Culture Dose/Concentration: 100 μ mol Time to Analysis: 2h | <p>Cell Viability: After 2 h of exposure, Zn^{2+} induced effects in NHBE cells at 100 and 200 μmol levels (but not 50 μmol). Continuing exposure to 100 μmol Zn^{2+} for 4 and 6 h did not significantly alter cell viability. Thus, in all subsequent studies, NHBE cells were treated with 100 μmol Zn^{2+}.</p> <p>Induced EGFR Phosphorylation: Exposure to 100 μM Zn^{2+} for 1-4 h induced phosphorylation of EGFR in NHBE cells. EGFR kinase inhibitor PD153035 (to determine if phosphorylation of EGFR was the result of autophosphorylation of activated EGFR tyrosine kinase activity) caused Zn^{2+}-induced phosphorylation to subside. Zn^{2+}-activity requires tyrosine kinase activity.</p> <p>EGFR Phosphorylation Pathway: To test whether Zn exposure results in ligand release, which in turn can activate phosphorylation, NHBE cells were pretreated with LA1 blocking antibody. Results showed significant suppression of Zn^{2+}-induced phosphorylation, therefore Zn^{2+}-phosphorylation might be initiated by the release of EGFR ligands.</p> <p>HB-EGF, TGF-α, EGF: To examine the involvement of specific ligands (HB-EGF, TGF-α and EGF) in the phosphorylation pathway, cells were exposed to anti-HB-EGF, anti-TGF-α and anti-EGF. Results showed that anti-HB-EGF reduced Zn^{2+}-induced phosphorylation significantly, anti-TGF-α produced partial inhibition and anti-EGF had no inhibitory effect. Exposure with blocking antibody LA1 was tested to determine if it caused an increase in soluble HB-EGF. HB-EGF mRNA expression was also elevated in cells exposed to Zn^{2+}. Previous studies indicate metalloproteinase (MMP) involvement in cleaving ligand precursors. It was found that MMP-3 inhibitor partially blocks Zn^{2+}-induced HB-EGF release. (MMP-2 and MMP-9 did not show similar inhibition patterns) Zn^{2+}-exposure increased the release of MMP-3 from HNBE cells.</p> |

| Reference: Wu et al. (2005, 097350) Species: Human Cell Line: Subclone S6 Cell Type: BEAS-2B | Zinc Ion: Zn^{2+} Particle Size: NR | Route: Cell Culture Dose/Concentration: 50 $\mu\text{mol } Zn^{2+}$ Time to Analysis: 4 or 8h; EGFR phosphorylation: 30, 60, 120, 240 min | <p>Cell viability: Exposure to 50 $\mu\text{mol } Zn^{2+}$ for 8 h did not result in significant alterations in cell viability (assessed by LDH release).</p> <p>P13K/Akt signaling pathway: To evaluate P13K's on COX-2 Zn^{2+}-induced expression, LY-294002 (a P13 inhibitor) and another unnamed P13 inhibitor were used. Exposed cells indicated suppressed levels of Zn^{2+}-induced COX-2. To determine Akt role, ad-DN-Akt(AAA) was used. Infected cells indicated over-expression of Akt and significant reduction of Zn^{2+}-induced GSK-3α/β phosphorylation. Over expression of DN-Akt(AAA) blocked Zn^{2+}-induced COX-2 expression.</p> <p>PTEN's role in blocking Zn^{2+}-induced COX-2 mRNA expression: PTEN is an antagonist of P13/Akt pathway. Overexpression of wildtype PTEN blocked Zn^{2+}-induced mRNA COX-2 expression, suggesting PTEN inhibits PIP3 signal transduction to Akt.</p> <p>Analysis of the Src/EGFR signaling pathway: Zn^{2+} induced a time-dependent increase in Src and EGFR phosphorylation in cells. Blockage of Src activity via PP2 (Src inhibitor) decreased Zn^{2+}-induced EGFR phosphorylation. The EGFR tyrosine inhibitor completely blocked Zn^{2+}-induced EGFR phosphorylation. EGF (a ligand of EGFR signaling) induced COX-2 expression, suggesting that EGFR regulated Zn^{2+}-induced COX-2 expression.</p> <p>p-38 and EGFR kinase activity: Use of PD-153035 (EGFR inhibitor) and PP2 (Src inhibitor) and SB-203580 (p38 inhibitor) all blocked Zn^{2+}-induced Akt phosphorylation of Src., EGFR and p38. It is thought that p38 is a critical kinase in regulation of Zn^{2+}-induced COX-2 protein expression.</p> |

| Reference: Zhang et al. (2007, 156179) Species: Human, Rat Cell Type: A549, RLE-6TN (Alveolar Type II Epithelial Cells) | PM_{2.5}: Collected by baghouse from Dusseldorf, Germany Particle Characterization: Carbon 20%, Hydrogen 1.4%, Nitrogen < 0.5%, Oxygen 14.1%, Sulfur 2.1%, Ash 63.2%. Particle Size: PM _{2.5} | Route: Cell Culture Dose/Concentration: 100 µg/cm ² Time to Analysis: 24h | Apoptosis: At 100 µg/mL for 24 h, PM induced a 2.5 fold increase in apoptosis in A549. Mitochondrial Membrane Potential: A significant reduction in AEC mitochondrial membrane potential was observed. Caspase -3 & -9: Increased activity of both enzymes in both cell types was observed. More specifically, a 2- to 2.5-fold increase of caspase -3 and -9 in A549 and an 8-fold increase of caspase-9 and 4-fold increase of caspase-3 in RLE-6TN were observed. BIM: Downregulation of BIM by RNA interference inhibited PM-induced apoptosis. An inhibited decrease in mitochondrial membrane potential and activation of both caspases were observed. |
| Reference: Zhang et al. (2004, 157183) Species: Mice Cell Line/Type: C10 (alveolar type II-like epithelial cell line) | DEP: SRM 1650a Particle Size: NR | Route: Cell Culture Dose/Concentration: 5 or 25 µg/mL Time to Analysis: 30-360min | fra expression: DEP induces fra-1 but not fra-2 expression. mRNA induction peaks around 180 min DEP affects fra-1 mRNA expression at the transcriptional level. ERK/JNK/p38 MAPK signaling pathways: 3 inhibitors (PD-98059, SB-202190 or SP-600125) all reduced DEP stimulated fra-1 induction to near control levels. DEP stimulated phosphorylation of the MAPKs which peaks at 60 min but stays elevated at 180 min. MMP-9 promoter activity: fra-1 upregulation may play a role in DEP induced increases in MMP-9 promoter activity as fra-1 appears to bind at the -79 TRE sequence of the MMP-9 promoter. | Reference: Adamson et al. (2003, 087943) Species: Rat Gender: Male Strain: Sprague-Dawley Weight: 150g | PM₁₀: EHC-93W (whole dust) EHC-93S (soluble) EHC-93L (leached) EHC-2KW, -S, -L Measured components Zn, Mg, Pb, Fe, Cu, Al Particle Size: EHC-93W, -93S, -93L, -2KW, -2KS, -2KL: PM ₁₀ | Route: IT Instillation Dose/Concentration: 5 mg/rat; 33.3 mg/kg Time to Analysis: 4h, 1d, 3d, 7d, 14d | BALF Cells: The greatest increase in cell numbers was observed with EHC-93W. Activity peaked at 1d with a return to normal levels by 7d. EHC-93L also induced an increase in cell numbers, more so than EHC-93S, but both particles induced statistically significant increases. However, these increases were mostly attributable to an increase in the AM and PMN populations. BALF Inflammatory/Injury Markers: Metalloproteinase (MMP) 2 and 9 both increased, peaking at 1d and 4h respectively. MMP2 activity appears related to the soluble fraction whereas MMP-9 activity appears to be related to the leachable fraction. |

| Reference: Ahn et al. (2008, 156199) Species: Mouse Gender: Male Strain: BALB/C1 Age: 6wks Weight: 19-24g | DEP: Collected using a turbo-charged, intercooler, 6-cylinder, heavy-duty, diesel engine (model year 2000) DPBS: control Particle Size: NR | Route: Oropharyngeal Aspiration Dose/Concentration: 1, 10, 25 mg/kg per day; Those receiving 25 mg/kg DEP also received pre-treatment of Dex (1, 5 mg/kg) 1h prior Time to Analysis: 5 consecutive days; 72h post final exposure | BALF Inflammatory/Injury Markers: Lung injury was more severe in mice exposed to 25 mg/kg of DEP than when compared to mice exposed to 1 mg/kg DEP. However, lung injury caused by exposure to 25 mg/kg DEP could be completely prevented with pre-treatment of 5mg/kg Dex. Treatment with 1 mg/kg Dex prior to exposure to 25 mg/kg DEP depicted partial reduction in lung injury. BALF Cells: Treatment with DEP over a 5d period caused an increase in total number of cells (macrophages, neutrophils and lymphocytes) when compared to control. Total Cells: Control - 5.33 ± 0.44 cells 1mg/kg DEP - 6.26 ± 0.87 cells 10mg/kg DEP - 14.40 ± 1.90 cells 25 mg/kg DEP - 47.20 ± 3.40 cells COX-2 Expression: Exposure to DEP lead to a dose-dependent increase in COX-2 levels; specifically, treatment with 25 mg/kg significantly increased COX-2 levels. This effect was completely reduced by treatment with 5mg/kg of Dex. |
| Reference: Ahsan et al. (2005, 156200) Species: Mouse Gender: Male and Female Strains: hTrx-1-transgenic and C57BL/6 (control) Age: 8-8.5wks | DEP: Obtained from Dr. Masaru Sagai (Amori, Japan) Particle Size: NR | Route: Intratracheal Instillation Dose/Concentration: Lung Damage: 0.1 mg/mouse; Survival Analysis: 0.2 mg/mouse; ESR: 0.05 mg/mouse Time to Analysis: 24h | ESR: hTrx-1 induced 0.05 mg generation of hydroxyl radicals in the lungs (mid thorax ESR spectra) compared to control. BALF Inflammatory/Injury Markers: hTrx-1 attenuated cellular damage from 0.1mg DEP. Control mice showed massive edema with neutrophilic infiltration, hemorrhagic alveolar damage and collapsed air spaces. hTrx-1 mice showed mild/moderate edema with clear demarcation of air spaces. Viability: After 4, 12 and 24 h, survival was 32, 24 and 12% respectively as compared to 80, 52 and 40% for hTrx-1 mice. |
| Reference: Andre et al. (2006, 091376) Species: Mouse Gender: Female Strain: BALB/cJ Age: 10-12 wks | UFCP: Ultra Fine Carbon Particles (electric spark generator, Model GFG 1000; Palas, Karlsruhe, Germany) Measured Component: UFCP > 96% elemental carbon Particle Size: 49nm | Route: Whole-body Inhalation Dose/Concentration: $380 \mu\text{g}/\text{m}^3$ Time to Analysis: 4 and 24h; 0 and 24h post-exposure | BALF Cells: A small increase in PMN number suggests a minor inflammatory response after 24 h exposure. Number of macrophages did not increase. BALF Inflammatory/Injury Markers: Total protein concentration significantly increased post 24 h inhalation. Post 4h, heat shock proteins were induced. Post 24 h, immunomodulatory proteins (osteopontin, galectin-3 and lipocalin-2) significantly increased in alveolar macrophages and septal cells. 236 (1.9%) genes was increased and 307 (2.5%) genes were decreased with upregulated genes being primarily related to the inflammatory process. |
| Reference: Antonini et al. (2004, 097199) Species: Rats Gender: Male Strain: Sprague-Dawley Weight: ~ 250g | ROFA-P: Precipitator -S: Soluble (0.22 μm filter), Components: Fe, Al, Ni, Ca, Mg, Zn -I: insoluble, Components: Fe, Al, Ni, Ca, Mg, Zn, V -T: total ROFA-AH: Air Heater -S: Soluble (0.22 μm filter), Components: Fe, V, Ni, AL -I: Insoluble, Components: Fe, V, Ni, AL -T: Total Particle Size: mean diameter: < 3 μm | Route: IT Instillation Dose/Concentration: 1mg/100g bw in 300 μl saline; 60mg/kg Time to Analysis: 24h; Clearance Experiment: two single exposures day 0 and 3 observed at day 6, 8 and 10 | ESR: Only ROFA-P contained free radicals, primarily in ROFA-P-S. BALF Cells: No effects on alveolar macrophages were observed, but all ROFA-P fractions increased lung neutrophils. ROFA-P-S and ROFA-P-I effects combined roughly equaled ROFA-P-T. BALF Inflammatory/Injury Markers: ROFA-AH-T and ROFA-AH-I increased LDH. ROFA-P and -AH increased albumin for T and I fractions. Pulmonary Clearance (Listeria Monocytogenes): ROFA-P-T and ROFA-P-S significantly slowed bacteria clearance from lungs. ROFA-AH and ROFA-P-I had no effect. |

Smaller doses of RER and DEP induced no effect. CB induced no effect. BALF Inflammatory/Injury Markers: 100 μ g RER increased BALF protein after 8 h. No effect was observed after 24 h nor with smaller doses of PM. RER significantly increased MMP-12 mRNA level after 8h and HO-1 total lung mRNA content. No effects on MMP-2 or -9 or TIMP-1 or -2 expression were observed. No effects from CB or DEP were observed. Cytokines: 100 μ g RER increased BAL, TNF- α and MIP-2 protein content after 8 h. |
| Reference: Becher et al. (2007, 097125) Species: Mouse Strain: Crl/Wky (iNOS(-/-)) and C57Bl/6, Gender: Male Age: 8-14wks Weight: 25g | Suspended PM: SRM-1648 Particle Size: NR | Route: IT Instillation Dose/Concentration: 1.6 μ g/lung; 64 mg/kg Time to Analysis: 20h | Cytokines: In both wild and KO strains, all particles caused increases of IL-6, MIP-2 and TNF- α levels. NADPH-oxidase KO mice showed significantly lower levels of IL-6 and MIP-2 responses to SPM comparatively to wildtype. iNOS KO mice showed significantly reduced IL-6, TNF- α , MIP-2 responses to SPM comparatively to wildtype. Free Radicals: SPM induced significant increases in free radical formation in alveolar type 2 cells but could be inhibited by DPI. |
| Reference: Bhattacharyya et al. (2004, 088095) Species: Mouse Strain: Sprague-Dawley Weight: 200-250g | Douglas Fir Wood Smoke (generated by burning wood at 400 $^{\circ}$ C in crucible oven) Particle Size: NR | Route: Nose-only Inhalation Dose/Concentration: 25g/mouse Time to Analysis: Various exposure periods (0, 5, 10, 15, 20 min). Parameters measured after 24h recovery period. | Biochemical Parameters: Lipid peroxidation increased after 20 min of woodsmoke inhalation as did Myeloperoxidase at 20 min. No effects were observed at other times or for total antioxidant status, reduced or oxidized glutathione. Antioxidant Enzyme Activities: No effect was observed. Histology: Dose-dependent damage progressing from loss of cilia (5 min), degeneration of mucosal epithelium, loss of mucosal epithelium to disrupted mucosal epithelium with submucosal edema and inflammation. Changes persisted for up to 4 days. |
| Reference: Cao et al. (2007, 097491) Species: Rat Strain: SH and WKY Age: 12wks | PM _{2.5} (Thermo Anderson G-2.5 sampler, Shanghai, China) Components: As, Cd, Cr, Cu, Fe, Ni, Pb, Zn, V, Ba, Se, Mg, Co, Mn Particle Size: PM _{2.5} | Route: IT Instillation Dose/Concentration: 1.6, 8.0 and 40 mg/kg Time to Analysis: Exposed 1/d for 3d, sacrificed 24h following last exposure | BALF Inflammatory/Injury Markers: LDH activity and TBARS increased a in dose-dependent manner. Notably, activity in SH rats was much higher than WKY at the same dose exposed for each dose level. BALF Cells: PM decreased macrophages and increased neutrophils and lymphocytes in a dose-dependent manner. For the same exposed dose, WKY rats had a higher percentage than SH but a smaller percentage of neutrophils and lymphocytes. Cytokines: PM induced pro-inflammatory cytokine release (IL-1 β , TNF- α , CD44, MIP-2, TLR-4, OPN). Again, SH cytokine level was greater than WKY at all dose levels. PM induced anti-inflammatory cytokines CC16 and HO-1 in a similar manner but at much lower rate. |

| Reference: Carter et al. (2006, 095938) Species: Rat, Mouse, Hamster Gender: Female (all) Strain: F-344 (rat), B6C3F1 (mouse), Syrian Golden (hamster) Age: 7-10wks (all) | Pollutant: CB: Printex 90 Particle Size: primary size: 17nm; 1.2-1.6 μm (aerosol aerodynamic diameter) | Route: Whole-body Inhalation Dose/Concentration: 1, 7, 50 mg/m^3 Time to Analysis: 6h/day for 5d/wk for 13 wks; 1d, 3m, 11m post-exposure | <p>Superoxide: Levels rose in all species at 50mg dose. Hamsters had no increase at 7 and 1mg doses. Mice also increased at 7mg. Rats significantly increased at all dose levels. Rats maintained elevation except for the 50mg dose at 11mo postexposure; it declined but was still higher than control. Mice maintained elevation at 50mg while 7 mg returned to control levels by 3mo postexposure.</p> <p>H2O2: At 50mg, increased levels in all species, with the highest in rat, were observed. At 7mg, increased levels in rats and mice were initially seen but levels returned to baseline by 11mo. Hamster levels were not significant. At 1mg, no significant changes were observed.</p> <p>NO: Induced similar reactions as H2O2. Rat response continued through the study while mice and hamsters returned to baseline by 11mo postexposure. Rats produced significantly higher levels at all times than other species.</p> <p>BALF Cells: CB induced significant increases in neutrophils at 7 and 50mg for all species. Rats had the highest and most prolonged PMN response. Mice and hamsters had very similar reactions.</p> <p>Cytokines: TNF-α, MIP-2 and IL-10 increased in a dose-dependent manner in rats and mice. Hamsters increased for IL-10 only. MIP-2 levels were highest in rats. TNF-α level were similar in all three species at 50mg, but hamsters started with a markedly higher basal level.</p> <p>Glutathione Peroxidase: Hamsters were the most responsive with significant increases at all levels. Rats and mice increased at 50mg and continued to increase for up to 11mo. Hamster levels declined with time but continued to be higher than control.</p> <p>Glutathione Reductase: Rats increased only at 50mg and remained elevated for up to 11mo. Mice increased at 7 and 50mg and remained elevated for up to 11mo. Hamsters increased at all levels at 11mo, but at 50mg, levels only increased post 1d.</p> <p>Superoxide Dismutase: All species reacted in a dose-dependent manner. Rats were the least responsive. Rat SOD activity increased over time while rat and mouse activity decreased at 50mg. Data were consistent with cytokine data.</p> <p>Summary: Rats appear to produce proinflammatory responses while mice and hamsters produce antiinflammatory responses.</p> |
| Reference: Cassee et al. (2005, 087962) Species: Rat Gender: Male Strain: Wistar (SPFHsdCpb: WU) and SH/NHsd Age: 7 wks and 8-12wks | Pollutant: CAPs: PM _{2.5} Netherland suburban, industrial and freeway tunnel site collections Wistar rats pre-exposed to ozone SO ₄ , NO ₃ and NH ₄ ions: 54 \pm 4% suburban, 53 \pm 7% industrial and 35 \pm 5% freeway site conc of total CAPS mass Particle Size: PM _{2.5} (0.15 < PM < 2.5 μm) | Route: Nose-only Inhalation Dose/Concentration: PM 365-3720 $\mu\text{g}/\text{m}^3$ (results from 16 different exposures 2000, 2002); O ₃ : 1600 $\mu\text{g}/\text{m}^3$ (0.8 ppm) Time to Analysis: 8h O ₃ pre-exposure; 6h CAPS exposure; 48h post-exposure | <p>BALF Cells: Wistar exhibited increased protein, albumin, NAG and decreased ALP activity and macrophage numbers. Wistar showed increased PMNs due to ozone, but was not significantly increased with additional CAPs exposure. SH showed no effect of CAPS except for the increased PMNs.</p> <p>BALF Inflammatory/Injury Markers: No effect on AL, LDH, Glutathione, GSSG, GSH, Uric Acid was observed.</p> <p>Cytokines: No effect on IL-6, MIP-2 or TNF-α was observed. CAPs induced an increase in CC16 plasma of SH rats.</p> <p>Hematology: CAPS induced an increase in RBC, HGB and HCT of Wistar rats and fibrinogen of SH rats.</p> <p>Histology: Wistar and SH rats had no obvious lung abnormalities. Small changes include increased macrophages and cellularity of centriacinar septa of ozone-only rats. Both ozone-only and ozone + CAPS showed bronchial epithelium hypertrophy and perivascular influx of PMNs.</p> <p>BrdU Labeling Index of Terminal Bronchiolar Epithelium: No CAPs effects were observed.</p> |

| Reference: Chang et al. (2005, 097778) Species: Mouse Gender: Male Strain: ICR Age: 5wks Weight: 25-30g | UFCB: Ultrafine CarbonBlack - Printex 90 (Degussa) Particle Size: 14nm | Route: IT Instillation Dose/Concentration: 200µg/100ul/mouse Time to Analysis: Parameters measured 4, 16, 21, 42h post single exposure | BALF Cells: Neutrophil number was at control level at 4h, increased after 16h, peaked at 21h and returned to normal at 42h. No effect was observed for the macrophage count. BALF Inflammatory/Injury Markers: UfCB increased total protein with peak at 21h. Cytokines: TNF-α increased at 4h and returned to normal at 16h. VEGF (Vascular Endothelial Growth Factor): Increased at 4h and peaked at 16h but remained elevated at 21 and 42h. VEGF and total protein in BALF were correlated (R2 = 0.7352). ROS: Pretreatment with NAC (ROS inhibitor) decreased induction of BALF VEGF and total protein by UfCB but did not fully block its effect. Histology: Thickened alveolar walls in lungs of UfCB-treated mice 16h post-IT was observed. |
| Reference: Chang et al. (2007, 097475) Species: Mouse Gender: Male Strain: ICR Age: 5wks Weight: 25-30g | UFCB: Ultrafine Carbon Black - Printex 90 (Degussa) Particle Size: 14nm diameter | Route: IT Instillation Dose/Concentration: 200 µg/mouse; 8mg/kg Time to Analysis: Pretreatment with NAC (N-acetylcysteine) ip 320 mg/kg, 2-h before UFCB IT. Parameters measured 24h post exposure. | BALF Cells: Increased relative lung weight, total protein (2 fold), total cells (11 fold) and number of neutrophils were observed. BALF AM count was not affected. BALF Inflammatory/Injury Markers: Of the 33 identified proteins, the following 6 were confirmed and validated: Cp (ceruloplasmin), albumin, EGFR, LIFR (leukemia inhibitory factor receptor), α2M and β-actin. All were increased following UFCB exposure. The following were also identified: 3 membrane proteins, 3 intracellular proteins, 10 protease inhibitors and 6 antioxidants. UfCB increased LIFR and EGFR in BALF. UfCB significantly reduced EGFR and LIFR in lung homogenate. UfCB did not affect EGFR protein but down-regulated LIFR in A549 cells treated with UfCB. Antioxidant: Pretreatment with NAC reduced the intensity of albumin and α2M bands in BALF as well as most other proteins. Statistical analysis showed positive correlation between VEGF and albumin (R2 = 0.796) and VEGF and α2M (R2 = 0.7331) in BALF. |
| Reference: Cho et al. (2005, 156344) Species: Mouse Gender: Male Strains: DBA/2J, 129P3/J, C57BL/6J, BALB/cJ, A/J, C3H/HeJ, C3H/HeOuj Age: 6-8wks | ROFA: Obtained from Power unit 4, Boston, MA Absent of LPS Particle Size: NR | Route: IT Instillation Dose/Concentration: 6mg/kg bw (150µg in 50µl/ 25g) Time to Analysis: 24h; Additional HeJ and OuJ mice: single: 1.5, 3 and 6h (compare TLR-mediated molecular events) | BALF Cells: Significant genetic effects on number of macrophages and PMNs after ROFA challenge. For PMNs, DBA/2J, C57BL/6J, BALB/cJ, and 129P3/J all induced increases significantly higher than C3H/HeJ. For macrophages, only the A/J strain induced increases significantly higher than C57BL/6J. Total protein, PMNs and macrophages all increased with HeOuj inducing increases significantly different from HeJ. BALF Inflammatory/Injury Markers: Significant genetic effect on mean total protein concentration was observed. In decreasing order, DBA/2J, 129P3/J and C57BL/6J all induced increases significantly higher than C3H/HeJ. TLR4 mRNA Expression: A significant decrease was observed in TLR4 transcript level in HeJ- ROFA exposed mice post 1.5h. Post 6h, TLR4 levels were greater than the control levels. OuJ expression increased beginning 1.5h post exposure. TLR4 Protein Level: Protein level of OuJ mice significantly exceeded (~ 2-3 fold) HeJ mice at 1.5, 3 and 6h. Activation of Downstream Signal Molecules: Greater activation of MYD88, TRAF6, IRAK-1, NF-KB, MAPK, and AP-1 was observed in OuJ mice than in HeJ mice before the development of ROFA-induced pulmonary injury. Cytokines: IL-1β, LT-β, IL-1α, IL-7, IL-13, IL-16 increased in both strains (OuJ and HeJ). Levels of all cytokines above were significantly higher in OuJ than in HeJ. |

| Reference: Churg et al. (2003, 087899) Species: Human Gender: Female (Mexico City); Male, Female (Vancouver) Strain: -- Age: 66 ± 9yrs (Mexico City); 76 ± 11yrs (Vancouver) Weight: NR | PM (Mexico City- high PM region, Vancouver- low PM region) Particle Size: Geometric mean size of individual particles in tissue: 0.040-0.067 μm ; Aggregates in tissue: 0.34-0.54 μm ; Mexico City: 2.5, 10 μm | Route: Ambient Air Exposure. Autopsy Tissue. Dose/Concentration: 10 · > 1000X10 ⁶ g dry tissue; Mexico City: PM ₁₀ : 66 $\mu\text{g}/\text{m}^3$, Vancouver: PM ₁₀ : 25 μg , PM _{2.5} : 15 μg Time to Analysis: Lung samples taken from deceased lifelong Mexico City residents and Vancouver residents > 20yrs. Subjects were never-smokers, did not work in dust occupations or cook with biomass fuels. | The lungs from Mexico City residents showed increased muscle and fibrous tissue in the membranous bronchioles and respiratory bronchioles compared to the Vancouver residents. Pigmented dust, luminal distortion and carbonaceous aggregates of UFPs were present in the Mexico City lungs. |
| Reference: Costa et al. (2006, 088438) Species: Rat Gender: Male Strain: Sprague-Dawley Age: 60d | ROFA FP&L plant #6 oil, 1% sulfur Particle Size: ~ 1.95 μm | Route: ITInstillation vs Nose-only Inhalation (IH) Dose/Concentration: IT = 110 $\mu\text{g}/\text{rat}$ IH = 12 mg/m^3 Time to Analysis: IT = single IH = 6h 24, 48, 96h (histopath 24 and 48 only) | ROFA distribution: IH and IT resulted in equivocal distribution ($\mu\text{g}/\text{g}$ lung tissue) in 5 different lung lobes. Airway Hyperactivity: IT resulted in doubled airway hyperreactivity at 24 h which was sustained for 96h. IH hyperreactivity did not reach statistically significant level. BALF Inflammatory/Injury Markers: IH and IT showed very similar responses ($R^2 = 0.98$). Time-dependent increases were observed for protein and LDH. BALF Cells: Neutrophils peaked at 24 h and slowly declined at 48 and 96h. Lung Pathology: IT showed more alveolitis, bronchial inflammatory and fibrinous fluid infiltrate. IH showed relatively more congestion of small airways and alveolar hemorrhage. |
| Reference: Courtois et al. (2008, 156369) Species: Rat Gender: Male Strain: Wistar Age: 12-14wks Weight: NR | PM (SRM 1648; 63% inorganic carbon, 4-7% organic carbon, > 1% mass fraction- Si, S, Al, Fe, K, Na) Carbon black (FW, P60) UF, fine TiO ₂ Particle Size: PM mean diameter: 0.4 μm ; Carbon black: FW- 13nm, P60- 21nm; TiO ₂ mean diameter: 0.14 μm | Route: IT Instillation Dose/Concentration: 5mg PM or TiO ₂ Time to Analysis: I.P injected then instilled. 6-72h recovery period then killed and lungs removed. | Particles were present in lung parenchyma that was removed 12 and 72h postinstillation. The Ach relaxation response significantly decreased in the 12h recovery period group but not in the other groups. Fine TiO ₂ did not alter Ach relaxation. |
| Reference: Dick et al. (2003, 036605) Species: Mouse Gender: Female Strain: CD1 Age: 8-10wks Weight: 20-25g | CO: PM Coarse FI: PM Fine FU: PM ultrafine PM collected in RTP, NC Particle Size: CO: 3.5 - 20 μm ; FI: 1.7- 3.5 μm ; FU: < 1.7 μm | Route: IT Instillation Dose/Concentration: 10 μg , 50 μg , 100 $\mu\text{g}/\text{mouse}$; 0.5, 2.5, 5.0mg/kg Time to Analysis: DMTU 500 mg/kg bw 30 min pre-exposure for some mice. Parameters measured 18h post-exposure. | Particle Characteristics: S increased (CO- 33.20 $\mu\text{g}/\text{mg}$, FI- 49.44 $\mu\text{g}/\text{mg}$ FU- 122.79 $\mu\text{g}/\text{mg}$) with decreasing particle size (mostly in the water-soluble fraction). Fe and Cu higher in coarse and fine fractions (mostly present in the insoluble). CO PM contained more nickel (in both soluble and insoluble) than FI or FU particles. Also, endotoxin levels similar in CO and FI; much lower in FU (0.165 EU/mg). BALF Cells: PMN increased with exposure for all 3 fractions except 100 μg FI. BALF Inflammatory/Injury Markers: Albumin increased only at 100 μg FI. No differences in NAG or LDH observed. Cytokines: IL-6 increased at 100 μg dose for all 3 fractions with similar responses. TNF- α increased a 100 μg dose of fine PM vs control. Effect of PM After Pre-treatment w/ DMTU: Systemic administration of DMTU alone depicted a two-fold increase in total antioxidant capacity. DMTU halved neutrophil response observed with PMs alone: No fractions were increased over DMTU alone which was at least two-fold saline control. IL-6 concentrations were drastically reduced in the DMTU group for the mice exposed to coarse particles (all fractions were reduced but only coarse had a significant response). TNF- α levels were decreased after treatment with particles and DMTU but treatment with particles and saline (control) produced similar results. |

| Reference: Dybdahl et al. (2004, 089013) Species: Mouse Gender: Female Strain: BALB/CJ or trans-genic (MutaMouse) Age: 9-10wks Weight: ~20g | DEP: SRM 1650 (NIST) Particle Size: DEP: NR; Control: PM 0.13 μ m diameter | Route: Nose-only Inhalation Dose/Concentration: I: 20 & 80 mg/m ³ II: 5 & 20 mg/m ³ Time to Analysis: I: single exposure 90min; II: 90 min/day for 4d; I & II: parameters measured 1, 3, or 22h post exposure | Cytokines: A single 90-min DEP exposure increased IL-6 gene level dose-dependently in the lung. For 80 mg/m ³ DEP, significantly higher IL-6 gene level was observed, both 1 and 22h post exposure. For 20 mg/m ³ DEP, a significantly higher IL-6 level was observed at 1 h post exposure but normalized at 3h. BALF Cells: Inhalation of DEP did not decrease viability of BAL cells (see Table1). For mice exposed to 20 mg/m ³ DEP, at 1 h post exposure in BAL fluid there was 3 fold increase in total cell number. DNA Damage: Level of 8-oxodG increased post single exposure with 80 mg/m ³ inducing levels significantly higher than controls. Repeated exposures were associated with significantly higher DNA strand breaks. |
| Reference: Elder et al. (2004, 055642) Species: Rat Gender: Male Strain: Fisher344, SH Age: 23m (Fisher), 11-14m (SH) | UFP: argon-filled chamber with electric arc discharge (TSI, Inc., St. Paul, MN) Particle Size: 36nm | Route: Whole-body Inhalation. Intraperitoneal (ip) for saline and LPS Dose/Concentration: UFP: 150 μ g/m ³ bw; LPS: 2 mg/kg Time to Analysis: Parameters measured post single exposure of 6h, 18h | BALF Cells: Neither inhaled UFP nor LPS cause a significant increase in BAL fluid total cells or percentage of neutrophils in either rat strain. No significant exposure-related alteration in total protein concentration was observed. In both rat strains LPS induced a significant increase in the amount of circulating PMNs. When combined with inhaled UFP, PMNs decreased; for F-344 rats, this decrease was significant. BALF Inflammatory/Injury Markers: Plasma fibrinogen increased with LPS in both rat strains with the magnitude of change greater in SH rats. UFP alone decreased plasma fibrinogen in SH rats. Combined UFP and LPS response was blunted but significantly higher than controls. Hematocrit was not altered in either rat strain by any treatment. No change in activities of LDH and b-glucuronidase was observed. TAT complexes: With all exposure groups averaged, plasma TAT complexes in SH rats were 6.5 times higher than in F-344 rats. LPS caused an overall increase in TAT complexes for F-344 rats which was further augmented by inhaled UFP. UFP alone induced a decreased response. In SH rats, UFP alone exhibited a significantly increased response and LPS exhibited a decreased response. ROS in BALF: In F-344 rats, both UFP and LPS have independent and significant effects on DCFD oxidation. Effects were in opposite directions; particles decreased ROS whereas LPS increased ROS. |
| Reference: Elder et al. (2004, 087354) Species: Rat Gender: Male Strain: F344 Age: 21m | Freshly generated vehicle exhaust emissions from I-90 between Rochester and Buffalo, NY Particle Size: NR | Route: Whole-body Inhalation; (IT Instillation: Influenza) Dose/Concentration: Vehicle exhaust: 0.95-3.13 x 10 ⁵ particles/cm ³ Endotoxin: 84 EU Influenza (IV): 10, 000 EID 50 in 250ul Time to Analysis: 1x6h, 3x6h or both. Parameters measured 18h post-exposure. 48h prior to on-road exposures, instilled intratracheally with IV. Immediate pre-exposure of priming agent endotoxin. EXPERIMENTS 1: LPS + PM 6 h 2: LPS + PM 6h, 3 x 6h 3: IV + PM 6 h 4: IV + PM 6h, 3x 6 h | No departures from normal baseline cellular or biochemical values were observed, suggesting that on-road exposures were well tolerated by the rats. BALF Inflammatory/Injury Markers: Increase in total protein concentration, LDH and B-glucuronidase activities were observed. Specific results according to groups 1-4 are as follows: Experiment 1: No endpoints revealed significant differences between groups of rats exposed to gas phase only versus the gas-phase/particle mixture. Experiment 2: Combination of endotoxin and particles produced greater inflammatory responses than those treated with saline and particles post 1d. After 3 days, no statistically significant changes were noted. Experiment 3: Influenza virus significantly increased ROS release in BAL cells. Experiment 4: Influenza virus significantly increased both percentage of PMNs in lavage fluid and BAL cell ROS release. |

| Reference: Elder et al. (2005, 088194) Species: Rat, Mouse, Syrian Golden Hamster Gender: Female Strain: F-344, B6C3F1, FIB | HSCb: Printex-90 high surface area carbon black, Deguss-Huels (Trostberg, Germany). LSCb: Sterling V, low surface area carbon black, Cabot (Boston, MA) Particle Size: HSCb = 14nm, LSCb = 70nm | Reference: Whole-body Inhalation Dose/Concentration: 0, 1, 7, 50 mg/m ³ HSCb; 50 mg/m ³ LSCb (rats only) Time to Analysis: 6 h/d, 5 d/wk for 13wks. Parameters measured 1d, 3mo, 11mo post-exposure | Body Weight: Environmental changes pre and post-exposure affected test subjects' life spans, particularly hamsters. Hamsters also experienced significant loss of body weight when exposed to high doses of HSCb. Effects of Carbon Black: In rats, lung weight of the high dose HSCb doubled. After 11mo, analysis of all lungs showed no significant difference. Mice had the highest relative lung burdens at the end of exposure time but also cleared particles faster at high doses than rats. However, clearance slowed over the 11mo recovery period, especially in high dose mice. Hamsters showed significant elevations in lung carbon black burden for all exposures at all time points. Hamsters exposed to high dose HSCb exhibited impaired clearance. BALF Cells: Presence of PMNs was limited to the mid and high dose groups. Overall maximal response was reached in mice and hamsters, but not in rats with increasing mass dose of HSCb. |
| Reference: Evans et al. (2006, 097066) Species: Rat Gender: Male Strain: Sprague-Dawley | DEP: collected under dry, outdoor, ambient conditions from tractor exhaust pipe (1985, Japanese ISEKI 1500 cc tractor) burning Esso 2000 diesel and 20/30 mixture of Esso light engine oil. 10% UF, 90% fine Cabosil: amorphous silicon dioxide 16% UF, 84% fine Particle Size: DEP: 30nm; Cabosil: 7nm | Route: IT Instillation Dose/Concentration: 1mg/rat DEP; 1mg/rat Cabosil Time to Analysis: Pretreatment with 0.5 unit of bleomycin; IT 3 or 7d after pre-treatment; 1wk post-IT | Lung permeability: In bleomycin-treated group, obvious inflammatory status and edema within the lung was observed. This was shown by significant increases in acellular protein and free cells. Changes in lung: Body weight ratio, lung surface protein content, free cell counts, and apical surface protein of rat type I cells were only altered by bleomycin treatment and not particle exposure. |
| Reference: Finnerty et al. (2007, 156434) Species: Mouse Gender: Male Strain: C57BL/6J Age: 12 wks Weight: 24.3 ± 0.3g | Coal Fly Ash (generated at U.S EPA National Risk Management Research Laboratory by burning Montana subbituminous coal under conditions simulating full-scale utility boiler conditions) Transition metals of Coal Fly Ash: Fe, Mg, Ti, Mn, V Particle Size: > PM _{2.5} | Route: IT Instillation Dose/Concentration: PM: 200mg PM/mouse; 9.1 mg/kg PM + LPS10: 200mg PM + 10mg LPS PM + LPS100: 200mg PM + 100mg LPS LPS: 100 µg Time to Analysis: Parameters measured 18h post single exposure | BALF Cells: No significant differences in platelet concentration or white blood cell count in any groups were observed. The percentage of neutrophils increased significantly with PM + LPS100. PMN rose in PM groups and increased further with LPS treatment. Increases in PM + LPS were groups statistically significant. More leukocytes were present in the alveolar space in PM + LPS10 compared to the PM group. The most severe response was in the PM + LPS100 group. Cytokines: Plasma TNF-α and IL-6 significantly increased for the PM + LPS100 group. An additive effect of LPS and PM for IL-6 was observed. For saline and PM groups, pulmonary TNF-α was below detection range. A synergistic effect for TNF-α was observed. A less than additive effect for IL-6 was observed. Pulmonary TNF-α significantly increased in the PM + LPS100 group. Pulmonary IL-6 significantly increased in both PM + LPS groups. |
| Reference: Fujimaki et al. (2006, 096601) Species: Mouse Gender: Male Strain: IL-6(-/-) and WT: B6J129Sv (control) Age: 5-6wks | DEP: collected from a 4-cylinder, 2.74 L, Isuzu diesel engine Particle Size: 0.4 µm | Route: Whole-body Inhalation Dose/Concentration: 1.0, 3.0 mg/m ³ Time to Analysis: 12 h/d for 4wks. Parameters measured 1d post-exposure | BALF Cells: Treatment significantly increased BAL cells from WT mice at both dose levels. The increase of macrophages and neutrophils were dose-dependent. An increase in lymphocytes were present in WT mice with the low dose. No significant increase in cells were observed from IL-6 (-/-). Cytokines: TNF-α largely increased in IL-6(-/-) mice exposed to 3 mg/m ³ compared to WT mice. IL-6 production increased in WT mice exposed to 3 mg/m ³ . CCL3 increased in both WT and IL-6(-/-) at high dose. IL-1β remained at the control level. |

| Reference: Gerlofs-Nijland et al. (2007, 097840) Species: Rat Gender: Male Strain: SH/NHsd Age: 13wks Weight: 250-350g | PM samples collected from: 1. MOB high traffic density 2. HIA high traffic density 3. ROM high traffic density 4. DOR moderate traffic density 5. MGH low traffic density 6. LYC low traffic density Particle Size: Coarse: 2.5 - 10 μm ; Fine: 0.1 - 2.5 μm | Route: IT Instillation Dose/Concentration: 3, 10mg/kg Time to Analysis: 24h | <p>BALF Inflammatory/Injury Markers: LDH was significantly increased for all doses of coarse PM and for the high dose of fine PM. BALF protein concentration was observed predominantly at the high dose of coarse PM. Location ROM had evidence of attenuated responses with fine PM. Ascorbate concentrations were reduced but were only significant for rats exposed to the highest dose of coarse PM fractions from the locations MOD, HIA, and LYC.</p> <p>BALF Cells: Pulmonary inflammation was induced in a significant and dose-dependent manner for both dose levels. Inflammation in the BALF included airway neutrophilia, increased macrophage numbers and mild lymphocytosis. Both coarse and fine PM caused dose-dependent aveolitis. Fine PM from LYC (10mg/kg dose) also caused some bronchiolitis.</p> <p>Cytokines: TNF-α concentrations increased for all coarse samples with the exception of DOR and LYC. Fine PM induced similar responses for all sites. MIP-2 concentrations increased only at certain sites for coarse but not fine PM.</p> <p>Hematology: Fibrinogen responses of SH rats increased significantly at the high dose of both fractions of all PM samples, except fine PM from DOR.</p> <p>Location-related differences: Coarse PM from MOB, HIA and MGH induced higher LDH responses than other locations. Coarse PM from HIA produced BALF protein concentrations higher than LYC and ROM. MGH induced greater amounts of BALF protein than ROM. Coarse PM from LYC lowered fibrinogen values more than PM from location MOB, HIA, and MGH. Fine PM showed less differences among the various sites.</p> <p>Particle Correlation: Fine PM exhibited significant correlation between zinc content and BALF cytotoxicity markers protein and LDH - mainly from HIA. Fine PM also exhibited positive correlations with copper and barium. Coarse PM showed positive correlation with barium and copper, mainly from MOB.</p> |
| Reference: Gerlofs-Nijland et al. (2009, 190353) Species: Rat Gender: Male Strain: SH Age: 12wks Weight: 200-300g | PM (Prague, Czech Republic; Duisburg, Germany; Barcelona, Spain) (Prague and Barcelona coarse PM organic extracts) Particle Size: Coarse: 2.5-10 μm , Fine: 0.2-2.5 μm | Route: IT Instillation Dose/Concentration: 7mg PM/kg body weight Time to Analysis: DTPA added to some PM samples preinstillation. Instilled with PM. Necropsy 24h postexposure. | Inflammation (LDH, protein, albumin), cytotoxicity (NAG, MPD, TNF- α), and fibrinogen were increased by PM, and were greatest in the coarse PM fraction. Metal-rich PM had greater inflammatory and cytotoxic effects, and increased fibrinogen and vWF and decreased ACE. PAH content influenced greater inflammation (including neutrophils), cytotoxicity, and fibrinogen. Generally, whole PM and coarse PM were more potent than organic extracts and fine PM, respectively. |
| Reference: Ghio et al. (2005, 088272) Species: Rat Gender: Male Strain: N8 b/b Belgrade rats and N8 + lb Belgrade controls | Oil Fly Ash (Southern Research Institute, Birmingham, AL) Particle Size: 1.95 \pm 0.18 μm (MMAD) | Route: IT Instillation Dose/Concentration: 500 μg /rat; 2mg/kg Time to Analysis: 24h | <p>BALF Cells: Homozygous Belgrade with mutation G185R had higher levels of Fe and V 24 h post-exposure. This may demonstrate a decreased ability to remove Fe and V from the lower respiratory tract than heterozygous +lb littermates. This also indicates that DMT1 is normally responsible for at least some Fe and V uptake; thus, a defective DMT1 transports less.</p> <p>BALF Inflammatory/Injury Markers: Increased protein and LDH concentrations in the homozygous strain were observed when compared to control</p> |

| Reference: Ghio et al. (2005, 088275) Species: Rat Gender: Male Strain: Sprague-Dawley Age: 60d Weight: 250-300g | Ferric ammonium citrate (FAC) Vanadyl sulfate (VOSO ₄) Particle Size: NR | Route: IT Instillation Dose/Concentration: 0.5 mL 100 μ m FAC/rat; 0.5 mL 10 μ m VOSO ₄ /rat; 500 μ g oil fly ash; 2 mg/kg Time to Analysis: Single or double exposure with 24 h rest period. Parameters measured 15, 30, 60 min, 24h post-exposure. | DMT1 immunohistochemistry and lung injury: FAC increased and VOSO ₄ decreased –IRE DMT1 staining. Same exposures had no effect on +IRE DMT1. –IRE DMT1 expression in macrophages, airway and alveolar epithelial cells increased with increased Fe exposure. Vanadium nearly eliminated staining except in alveolar macrophages. Increased metal clearance with pre-exposure to FAC. Less metal clearance with pre-exposure to VOSO ₄ . Pre-exposure to iron diminished lung injury whereas pre-exposure to vanadium increased lung injury after oil fly ash instillation. Lung injury measured by concentration of protein and LDH in BAL. |
| Reference: Gilmour et al. (2007, 096433) Species: Mouse Gender: Female Strain: BALB/c Age: 10-12wks Weight: 20-22g | PM - CO, FI, UF (obtained from U.S. Seattle (S), Salt Lake City (SL), South Bronx (SB), Sterling Forest (SF)) SB: included 35% sulfate, 22% gasoline, diesel and brake wear. SF: 48% sulfate. SL: 34% wood combustion and 28% sulfate S: 39% wood combustion and 29% sulfate Residual oil combustion and soil dust less than 5% for all sites. Particle Size: CO: 2.5-10 μ m; FI: \square 2.5 μ m; UF: \square 0.1 μ m | Route: Oropharyngeal Aspiration Dose/Concentration: 25 μ g or 100 μ g PM; 1.25 or 5 mg/kg Time to Analysis: 18h | BALF Inflammatory/Injury Markers: Seattle CO fractions showed no dose-dependent effect on protein concentration. Results for other locations were distinctly higher with 100 μ g dose than 25 μ g and saline doses. SL CO high dose induced the most significant increase. LDH response was weakly dose-related. Only SB showed a statistically significant increase for LDH with the high dose UF. BALF Cells: PMN increased with the high dose of CO samples from SB, SL, S, but not SF. No significant increases from FI were observed, though the high dose induced increased PMN. UF from SL caused a highly variable response. Cytokines: MIP-2 was similar to PMN response. SB CO induced the most significant response. SL UF was highly variable. Particle Characteristics: LPS was higher in S (CO, FI, UF) and SL (CO, FI, UF). Zn levels were highest in SB (CO, FI, UF). Fe was higher in all CO and FI samples with SB CO inducing the highest. |
| Reference: Gilmour et al. (2004, 057420) Species: Mouse Gender: Female Strain: CD1 Age: 8-10wks Weight: 20-25g | Coal Fly Ash MU: Montana Ultrafine MF: Montana Fine MC: Montana Coarse KF: W. Kentucky Fine KC: W. Kentucky Coarse Particle Characteristics: Montana Sulfur 0.83%, Ash 11.72%. Trace amounts of Ba, P, Sr, V, Nb, Cd, Se, Ga, Cu. Depleted in Si, Al, Fe, Mg, Ti. Kentucky Sulfur 3.11%, Ash 8.07% Particle Size: Coarse: > 2.5 μ m; Fine: < 2.5 μ m; Ultrafine: < 0.2 μ m | Route: Oropharyngeal Aspiration Dose/Concentration: 25ug or 100 μ g/mouse Time to Analysis: 18h | BALF Cells: PMN highly increased for MU at both doses. The level was comparable to the positive control. PMN also increased with KF at high dose. Coarse particles caused no significant increase in PMN. Number of macrophages did not change, but NAG increased significantly with MU for both dose levels and with KF and MF at high dose level. BALF Inflammatory/Injury Markers: Total protein and LDH was not significantly elevated. Albumin concentration increased significantly after treatment with the fine high dose of both particle types. Cytokines: MU particles caused a significant increase in TNF- α . MIP-2 increased in all fine and ultrafine PM-instilled animals with the highest in the MU and KF at both doses. IL-6 was detectable only in the BALF of MU and KF with substantial variability. The IL-6 levels were not significant. |

| Reference: Gilmour et al. (2004, 087948) Species: Rat Gender: Male Strain: SH/NQIBR, WKY Age: 12wks Weight: 280-340g | PM (collected from precipitator unit of an oil burning power plant in Boston) Measured Components of PM: S, Zn, Ni, V, Al, Cu, Pb, Fe, Ca, Na, K, Mg, Endotoxin Particle Size: NR | Route: IT Instillation Dose/Concentration: 0.0, 0.83, 3.3, and 8.3 mg/kg in SH rats; 0.0 or 3.3 mg/kg in WKY and SH rats Time to Analysis: 24h | BALF Inflammatory/Injury Markers: LDH activity increased in a dose-related manner; this was observed in SH rats after exposure to 0.83, 3.33 and 8.3 mg/kg PM. SH rats showed greater lung permeability following PM exposure than WKY rats. SH rats showed acute lung inflammatory response after exposure to PM when compared to WKY rats. BALF Cells: No increase in macrophage number was observed in either rat strain following saline or PM exposure at 24 h. Cytokines: MIP2 mRNA expression increased significantly in SH PM exposure group only. No significant differences in TNF- α RNA expression in either WKY, SH rats or control treatment groups were observed. CD14: A significant increase in lung CD14 protein was observed only in SH rats exposed to PM. TLR4: A significant increase in TLR4 protein in SH rats exposed to PM was observed. NF-kB: A significant increase in NF-kB binding protein in the nuclei of SH rats exposed to PM was observed. This effect was not observed in the control of PM-exposed WKY rats. |
| Reference: Gilmour et al. (2004, 054175) Species: Rat Gender: Male Strain: Wistar Age: 12wks | uFCB: Ultrafine carbon black (Printex 90 (Degussa)) CB: (Huber 990, HR. Haefner and Co) Particle Size: uFCB: 14nm; CB: 260nm (primary particle diameter) | Route: Whole-body Inhalation Dose/Concentration: uFCB: 1.66 mg/m ³ fCB: 1.40 mg/m ³ Number concentrations uFCB: 52380 particles/cm ³ fCB: 3800 particles/cm ³ Time to Analysis: Exposed for 7 h. Sacrificed 0, 16 or 48h post-exposure. | BAL Cells: Total number of cells increased significantly in UfCB-exposed rats at 0 and 16 h. Recruitment of cells did not occur in response to CB exposure. PMNs increased significantly in the BALF of uFCB-exposed rats at 16 h. Leukocytes remained unchanged following CB exposure but increased significantly at 0 and 48 h post exposure to uFCB. Cytokine mRNA: A significant increase in BALF MIP-2 mRNA expression was observed at 48 h. No differences in MIP-2 mRNA levels were observed in the whole lung tissue. |
| Reference: Godleski et al. (2002, 156478) Species: Rat Gender: Male Strain: SD Age: NR Weight: 200-250g | CAPs (Boston; Harvard Ambient Particle Concentrator) Particle Size: 0.27 \pm 2.3 μ m (diameter) | Route: Inhalation Dose/Concentration: 73.5-733 μ g/m ³ Time to Analysis: Exposed 5h/d, 3d (consecutive). BAL 24h postexposure | PMNs significantly increased with CAPs exposure and also in relation to CAPs mass, Br, SO ₄ ²⁻ , EC, OC and Pb. An overall increase in pro-inflammatory mediators and decrease in immune enhancer and evidence of vascular endothelial responses occurred with CAPs exposure. |
| Reference: Gottipolu et al. (2009, 190360) Species: Rat Gender: Male Strain: Wistar Kyoto (WKY), SH Age: 14-16wks Weight: NR | DE (30-kW (40hp) 4-cylinder indirect injection Deutz diesel engine) (O ₂ : 20%, CO: 1.3-4.8ppm, NO: < 2.5-5.9ppm, NO ₂ : < 0.25-1.2ppm, SO ₂ : 0.2-0.3ppm, OC/EC: 0.3 \pm 0.03) Particle Size: Number Median Diameter: Low- 83 \pm 2nm, High- 88.2nm; Volume Median Diameter: Low- 207 \pm 2nm, High- 225 \pm 2nm | Route: Exposure Chamber Dose/Concentration: Low- 507 \pm 4 μ g/m ³ , High- 2201 \pm 14 μ g/m ³ Time to Analysis: Exposed 4h/d, 5d/wk, 4wks. Necropsied 1d postexposure. | DE increased neutrophils in a concentration-dependent manner, and GGT activity at the high dose. Particle-laden macrophages were found in DE-exposed rats. DE dose-dependently inhibited mitochondrial aconitase activity. DE caused 377 genes to be differentially expressed within WKY rats, most of which were downregulated, but none in SH rats. However, WKY rats had an expression pattern shift that mimicked baseline expression of SH rats without DE. These genes regulated compensatory response, matrix metabolism, mitochondrial function, and oxidative stress response. |
| Reference: Gunnison and Chen (2005, 087956) Species: Mouse Gender: Male Strain: DK (ApoE ^{-/-} , LDLr ^{-/-}) Age: 18-20wks | CAPS (Northeastern regional background) Ambient air copollutants measured O ₃ , NO ₂ Particle Size: 389 \pm 2nm | Route: Whole-body Inhalation Dose/Concentration: CAPS = 131 \pm 99 μ g/m ³ including O ₃ = 10 ppb and NO ₂ = 4.4 ppb Time to Analysis: 6h/d, 5d/wk for 4m (5/12/03-9/5/03). Sacrificed 3-4d post exposure. | Microarray Data: 13 genes in the heart tissue and 47 genes in the lung tissue were identified as possibly affected. Strict standards (1.5 fold response, 10 % false discovery rate) resulted in responses by only 1/13 genes (Rex3 - no known heart physiology) in the heart tissue and 0/47 genes in the lung tissue. Using more liberal response (nonstatistical) standards (1.5 fold only) and comparison of each CAPS animal with all 3 control animals (3x3 array) resulted in possible effects on 7 additional genes in the heart tissue and 37 genes in the lung tissue. |

|--|---|--|--|
| Reference: Gurgueira et al. (2002, 036535) Species: Rat Gender: Male Strain: Sprague-Dawley Weight: 250-300g | CAPs (Harvard Ambient Particle Concentrator) CB (C198 Fischer Scientific, Pittsburgh, PA USA) Composed of 85.9 ± 0.2% Carbon, 13.0 ± 0.2% O ₂ , 1.17 ± 0.2% Sulfur ROFA (Boston, MA USA oil-fired power plant) Particle Size: CAPs: 1-2.5 μm; CB: < 2.5 μm; ROFA: < 2.5 μm | Route: Whole-body Inhalation Dose/Concentration: 300 ± 60 μg/m ³ Time to Analysis: 1, 3, 5h CAPs Exposure followed by immediate post-exposure analysis. 5h CB, immediate analysis. 30min ROFA, Immediate analysis. | In situ Chemiluminescence(CL): Data show a significant increase in lung and heart CL at 5h. Lung CL increased linearly with time of exposure. Oxidants: CAPs-initiated oxidative stress was not detectable in those rats allowed to recover in room air after the simulated "peak" in particulate air pollution. Rats breathing particle-free filtered air for 3 days had significantly lower levels of oxidants. Exposure to inert CB did not exert oxidant effects on the heart and lung. BALF Inflammatory/Injury Markers: The water content of the lung and heart increased significantly upon exposure to CAPs but not to filtered air and increased as a function of length of exposure. Rats breathing CAPs also showed increases in LDH and CPK as a function of length of exposure. Antioxidant enzymes: Data showed an increase in SOD and catalase activities in both the lung and heart. The pattern of increase was tissue specific. |
| Reference: Hamoir et al. (2003, 096664) Species: Rabbit Strain: New Zealand Age: 12-16 wks Weight: 2.8 ± 0.5kg | PSC: Polystyrene particles, Carboxylate modified, 3 types PSA: Polystyrene particles, Amine modified, 1 type Particle Size: PSC: 24, 110 or 190nm (PSC24, PSC110, PSC190); PSA: 190nm | Route: IT Instillation Dose/Concentration: PSC24: 0.04 or 4 mg/rabbit PSC110, PSC190, PSA190: 4mg/rabbit Time to Analysis: 0, 30, 60, 90, 120min | Capillary Filtration Coefficient: A time-dependent increase correlating to total number of particles/surface area, not particle size, was observed. PSA induced a significant increase in microvascular permeability as compared to PSC. This suggests that the number of particles exposed should be considered an important parameter for measuring air quality rather than total particle surface area. |

| Reference: Happonen et al. (2007, 096630) Species: Mouse Gender: Male Strain: C57BL/6J Weight: 19-30g Age: 10-11wks | PMC (Coarse) PMF (Fine) PMUF (Ultrafine) Collected in 6 European cities: Duisburg, Prague, Amsterdam, Helsinki, Barcelona, Athens Particle Size: PMC: PM ₁₀ -2.5; PMF: PM _{2.5-0.2} ; PMUF: PM _{0.2} | Route: IT Instillation Dose/Concentration: PMC: 5.9-29.6 µg/m ³ ; PMF: 8.3-25.2 µg/m ³ ; PMUF: 2.7-6.7 µg/m ³ Dose-response: 1, 3, 10mg/kg Time course: 10 mg/kg Time to Analysis: 1. Dose-Response study: parameters measured 24h post exposure. 2. Time course study: parameters measured 4, 12, 24 h post single exposure (at 10 mg/kg). | <p>Total Cell Numbers: 1. For the dose-response study, all the PMC samples exhibited dose-dependent increases of total cell numbers. The 3 and 10 mg/kg doses of PMC induced statistically significant increases. At 10 mg/kg, only 2/6 samples induced statistically significant increases. No PMUF samples induced effects at any dose. 2. For the time-response study, no increases in cell numbers were shown at 4 h. Though the levels induced by PMC at 24 h were lower than at 12 h, both levels were statistically significant. PMF induced statistically significant increases only at 12 h for 4/6 samples. PMUF induced only 1 significant increase at 12 h; the 24 h time point was not tested.</p> <p>Total Protein/LDH: 1. The lower doses of 1 and 3 mg/kg did not induce significant increases in any of the PM samples, except for PMUF-Athens. All 6 samples of PMC, at 10 mg/kg, induced significant increases. At 10 mg/kg, 4/6 PMF samples induced significant increases. 2. At 4 h, none of the samples increased protein concentration. The PMC samples, excluding Prague, induced significantly higher concentrations at 12 h. At 24 h, only 3/6 PMC samples induced significant increases. Only 2 PMF samples induced significant increases at 12 and 24 h. At 12 h, effects induced by PMUF were minimal and inconsistent; the 24 h time point was not tested.</p> <p>Cytokine: 1. Only PMC induced dose-dependent responses that reached statistical significance at 10 mg/kg. PMF and PMUF induced minimal and inconsistent responses.</p> <p>TNF-α levels: 2. TNF-α levels increased significantly at 4 and 12 h by PMC. At 24 h, TNF-α levels returned to near control levels. PMF, at 4 h, induced statistically significant increases for 3/6 samples and significant increases in 2/6 samples at 12 h. No PMUF samples significantly increased TNF-α levels.</p> <p>IL-6: 2. PMC induced the highest IL-6 levels at 4 h. Levels at 12 and 24 h were reduced with 6/6 and 3/6 samples showing statistically significant increases, respectively. PMF showed a similar trend with 4 h inducing the highest levels that were reduced at 12 and 24 h. Of the PMUF samples, only the Helsinki and Duisburg samples induced statistically significant results at 4 and 12 h. Generally, the PMUF responses were negligible when compared to PMC and PMF.</p> <p>KC production: 2. All PMC samples induced the highest levels at 4 h. At 12 and 24 h, levels were reduced but 4/6 samples induced statistically significant levels. PMF showed a similar trend- the highest levels were induced at 4 h (in 3/6 samples). PMUF at 4 h showed small, though not significant, increases. At 12 h, only 2 samples showed statistically significant differences from the control; the 24 h time point was not tested.</p> |
| Reference: Harder et al. (2005, 087371) Species: Rat Gender: Male Strain: Wistar Kyoto Age: 14-17wks Weight: NR | Carbon UFP Particle Size: Diameter: 37.6±0.7nm | Route: Exposure Chamber Dose/Concentration: 180 µg/m ³ Time to Analysis: Telemeter implanted into peritoneal cavity. 10d recovery. 3d baseline reading. 24h exposure. 3d recovery. | Carbon UFP mildly but significantly elevated HR compared to the control. SDNN was significantly decreased during exposure. UFP induced mild pulmonary inflammation, significantly increased PMN, and increased the total protein and albumin concentrations. Particle-laden macrophages sporadically accumulated in the alveolar region. |

|--|---|--|--|
| Reference: Harkema et al. (2004, 056842) Species: Rat Gender: Male Strain: F344, BN Age: 10-12wks Weight: NR | CAPs (Detroit; July-Sept. 2000; Harvard Ambient Fine Particle Concentrator) Particle Size: 2.5 μm (diameter) | Route: Inhalation Exposure Chamber. IT Instillation. Dose/Concentration: 4d concentration: $676 \pm 288 \mu\text{g}/\text{m}^3$, 5d concentration: $313 \pm 119 \mu\text{g}/\text{m}^3$, July concentration: $16\text{--}185 \mu\text{g}/\text{m}^3$, September concentration: $81\text{--}755 \mu\text{g}/\text{m}^3$; IT Instillation- 200 μL (soluble and insoluble) Time to Analysis: F344 rats sensitized to endotoxin, BN rats to OVA. Exposed 10h/d 1, 4, 5d (consecutive). Another group of rats i.t instilled. Both groups killed 24h postexposure. | The retention of PM in the airways was enhanced by allergic sensitization. Recovery of anthropogenic trace elements was greatest for CAPs-exposed rats. Temporal increases in these elements were associated with eosinophil influx, BALF protein content and increased airway mucosubstances. A mild pulmonary neutrophilic inflammation was observed in rats instilled with the insoluble fraction but instillation of total, soluble or insoluble $\text{PM}_{2.5}$ in allergic rats did not result in differential effects. |
| Reference: Elder et al. (2004, 055642) Species: Rat Gender: Male Strain: Fisher344, SH Age: 23m (Fisher), 11-14m (SH) | UFP: argon-filled chamber with electric arc discharge (TSI, Inc., St. Paul, MN) Particle Size: 36nm | Route: Whole-body Inhalation. Intraperitoneal (ip) for saline and LPS Dose/Concentration: UFP: $150 \mu\text{g}/\text{m}^3$ bw; LPS: 2 mg/kg Time to Analysis: Parameters measured post single exposure of 6h, 18h | BALF Cells: Neither inhaled UFP nor LPS cause a significant increase in BAL fluid total cells or percentage of neutrophils in either rat strain. No significant exposure-related alteration in total protein concentration was observed. In both rat strains LPS induced a significant increase in the amount of circulating PMNs. When combined with inhaled UFP, PMNs decreased; for F-344 rats, this decrease was significant. BALF Inflammatory/Injury Markers: Plasma fibrinogen increased with LPS in both rat strains with the magnitude of change greater in SH rats. UFP alone decreased plasma fibrinogen in SH rats. Combined UFP and LPS response was blunted but significantly higher than controls. Hematocrit was not altered in either rat strain by any treatment. No change in activities of LDH and b-glucuronidase was observed. TAT complexes: With all exposure groups averaged, plasma TAT complexes in SH rats were 6.5 times higher than in F-344 rats. LPS caused an overall increase in TAT complexes for F-344 rats which was further augmented by inhaled UFP. UFP alone induced a decreased response. In SH rats, UFP alone exhibited a significantly increased response and LPS exhibited a decreased response. ROS in BALF: In F-344 rats, both UFP and LPS have independent and significant effects on DCFD oxidation. Effects were in opposite directions; particles decreased ROS whereas LPS increased ROS. |
| Reference: Elder et al. (2004, 087354) Species: Rat Gender: Male Strain: F344 Age: 21m | Freshly generated vehicle exhaust emissions from I-90 between Rochester and Buffalo, NY Particle Size: NR | Route: Whole-body Inhalation; (IT Instillation: Influenza) Dose/Concentration: Vehicle exhaust: $0.95\text{--}3.13 \times 10^5$ particles/ cm^3 Endotoxin: 84 EU Influenza (IV): 10, 000 EID 50 in 250 μL Time to Analysis: 1x6h, 3x6h or both. Parameters measured 18h post-exposure. 48h prior to on-road exposures, instilled intratracheally with IV. Immediate pre-exposure of priming agent endotoxin. EXPERIMENTS 1: LPS + PM 6 h 2: LPS + PM 6h, 3 x 6h 3: IV + PM 6 h 4: IV + PM 6h, 3x 6 h | No departures from normal baseline cellular or biochemical values were observed, suggesting that on-road exposures were well tolerated by the rats. BALF Inflammatory/Injury Markers: Increase in total protein concentration, LDH and B-glucuronidase activities were observed. Specific results according to groups 1-4 are as follows: Experiment 1: No endpoints revealed significant differences between groups of rats exposed to gas phase only versus the gas-phase/particle mixture. Experiment 2: Combination of endotoxin and particles produced greater inflammatory responses than those treated with saline and particles post 1d. After 3 days, no statistically significant changes were noted. Experiment 3: Influenza virus significantly increased ROS release in BAL cells. Experiment 4: Influenza virus significantly increased both percentage of PMNs in lavage fluid and BAL cell ROS release. |

| Reference: Elder et al. (2005, 088194) Species: Rat, Mouse, Syrian Golden Hamster Gender: Female Strain: F-344, B6C3F1, FIB | HSCb: Printex-90 high surface area carbon black, Degussa-Huels (Trostberg, Germany). LSCb: Sterling V, low surface area carbon black, Cabot (Boston, MA) Particle Size: HSCb = 14nm, LSCb = 70nm | Reference: Whole-body Inhalation Dose/Concentration: 0, 1, 7, 50 mg/m ³ HSCb; 50 mg/m ³ LSCb (rats only) Time to Analysis: 6 h/d, 5 d/wk for 13wks. Parameters measured 1d, 3mo, 11mo post-exposure | Body Weight: Environmental changes pre and post-exposure affected test subjects' life spans, particularly hamsters. Hamsters also experienced significant loss of body weight when exposed to high doses of HSCb. Effects of Carbon Black: In rats, lung weight of the high dose HSCb doubled. After 11mo, analysis of all lungs showed no significant difference. Mice had the highest relative lung burdens at the end of exposure time but also cleared particles faster at high doses than rats. However, clearance slowed over the 11mo recovery period, especially in high dose mice. Hamsters showed significant elevations in lung carbon black burden for all exposures at all time points. Hamsters exposed to high dose HSCb exhibited impaired clearance. BALF Cells: Presence of PMNs was limited to the mid and high dose groups. Overall maximal response was reached in mice and hamsters, but not in rats with increasing mass dose of HSCb. |
| Reference: Evans et al. (2006, 097066) Species: Rat Gender: Male Strain: Sprague-Dawley | DEP: collected under dry, outdoor, ambient conditions from tractor exhaust pipe (1985, Japanese ISEKI 1500 cc tractor) burning Esso 2000 diesel and 20/30 mixture of Esso light engine oil. 10% UF, 90% fine Cabosil: amorphous silicon dioxide 16% UF, 84% fine Particle Size: DEP: 30nm; Cabosil: 7nm | Route: IT Instillation Dose/Concentration: 1mg/rat DEP; 1mg/rat Cabosil Time to Analysis: Pretreatment with 0.5 unit of bleomycin; IT 3 or 7d after pre-treatment; 1wk post-IT | Lung permeability: In bleomycin-treated group, obvious inflammatory status and edema within the lung was observed. This was shown by significant increases in acellular protein and free cells. Changes in lung: Body weight ratio, lung surface protein content, free cell counts, and apical surface protein of rat type I cells were only altered by bleomycin treatment and not particle exposure. |
| Reference: Finnerty et al. (2007, 156434) Species: Mouse Gender: Male Strain: C57BL/6J Age: 12 wks Weight: 24.3 ± 0.3g | Coal Fly Ash (generated at U.S EPA National Risk Management Research Laboratory by burning Montana subbituminous coal under conditions simulating full-scale utility boiler conditions) Transition metals of Coal Fly Ash: Fe, Mg, Ti, Mn, V Particle Size: > PM _{2.5} | Route: IT Instillation Dose/Concentration: PM: 200mg PM/mouse; 9.1 mg/kg PM + LPS10: 200mg PM + 10mg LPS PM + LPS100: 200mg PM + 100mg LPS LPS: 100 µg Time to Analysis: Parameters measured 18h post single exposure | BALF Cells: No significant differences in platelet concentration or white blood cell count in any groups were observed. The percentage of neutrophils increased significantly with PM + LPS100. PMN rose in PM groups and increased further with LPS treatment. Increases in PM + LPS were groups statistically significant. More leukocytes were present in the alveolar space in PM + LPS10 compared to the PM group. The most severe response was in the PM + LPS100 group. Cytokines: Plasma TNF-α and IL-6 significantly increased for the PM + LPS100 group. An additive effect of LPS and PM for IL-6 was observed. For saline and PM groups, pulmonary TNF-α was below detection range. A synergistic effect for TNF-α was observed. A less than additive effect for IL-6 was observed. Pulmonary TNF-α significantly increased in the PM + LPS100 group. Pulmonary IL-6 significantly increased in both PM + LPS groups. |
| Reference: Fujimaki et al. (2006, 096601) Species: Mouse Gender: Male Strain: IL-6(-/-) and WT: B6J129Sv (control) Age: 5-6wks | DEP: collected from a 4-cylinder, 2.74 L, Isuzu diesel engine Particle Size: 0.4 µm | Route: Whole-body Inhalation Dose/Concentration: 1.0, 3.0 mg/m ³ Time to Analysis: 12 h/d for 4wks. Parameters measured 1d post-exposure | BALF Cells: Treatment significantly increased BAL cells from WT mice at both dose levels. The increase of macrophages and neutrophils were dose-dependent. An increase in lymphocytes were present in WT mice with the low dose. No significant increase in cells were observed from IL-6 (-/-). Cytokines: TNF-α largely increased in IL-6(-/-) mice exposed to 3 mg/m ³ compared to WT mice. IL-6 production increased in WT mice exposed to 3 mg/m ³ . CCL3 increased in both WT and IL-6(-/-) at high dose. IL-1β remained at the control level. |

| Reference: Gerlofs-Nijland et al. (2007, 097840) Species: Rat Gender: Male Strain: SH/NHsd Age: 13wks Weight: 250-350g | PM samples collected from: 1. MOB high traffic density 2. HIA high traffic density 3. ROM high traffic density 4. DOR moderate traffic density 5. MGH low traffic density 6. LYC low traffic density Particle Size: Coarse: 2.5 - 10 μm ; Fine: 0.1 - 2.5 μm | Route: IT Instillation Dose/Concentration: 3, 10mg/kg Time to Analysis: 24h | <p>BALF Inflammatory/Injury Markers: LDH was significantly increased for all doses of coarse PM and for the high dose of fine PM. BALF protein concentration was observed predominantly at the high dose of coarse PM. Location ROM had evidence of attenuated responses with fine PM. Ascorbate concentrations were reduced but were only significant for rats exposed to the highest dose of coarse PM fractions from the locations MOD, HIA, and LYC.</p> <p>BALF Cells: Pulmonary inflammation was induced in a significant and dose-dependent manner for both dose levels. Inflammation in the BALF included airway neutrophilia, increased macrophage numbers and mild lymphocytosis. Both coarse and fine PM caused dose-dependent aveolitis. Fine PM from LYC (10mg/kg dose) also caused some bronchiolitis.</p> <p>Cytokines: TNF-α concentrations increased for all coarse samples with the exception of DOR and LYC. Fine PM induced similar responses for all sites. MIP-2 concentrations increased only at certain sites for coarse but not fine PM.</p> <p>Hematology: Fibrinogen responses of SH rats increased significantly at the high dose of both fractions of all PM samples, except fine PM from DOR.</p> <p>Location-related differences: Coarse PM from MOB, HIA and MGH induced higher LDH responses than other locations. Coarse PM from HIA produced BALF protein concentrations higher than LYC and ROM. MGH induced greater amounts of BALF protein than ROM. Coarse PM from LYC lowered fibrinogen values more than PM from location MOB, HIA, and MGH. Fine PM showed less differences among the various sites.</p> <p>Particle Correlation: Fine PM exhibited significant correlation between zinc content and BALF cytotoxicity markers protein and LDH - mainly from HIA. Fine PM also exhibited positive correlations with copper and barium. Coarse PM showed positive correlation with barium and copper, mainly from MOB.</p> |
| Reference: Gerlofs-Nijland et al. (2009, 190353) Species: Rat Gender: Male Strain: SH Age: 12wks Weight: 200-300g | PM (Prague, Czech Republic; Duisburg, Germany; Barcelona, Spain) (Prague and Barcelona coarse PM organic extracts) Particle Size: Coarse: 2.5-10 μm , Fine: 0.2-2.5 μm | Route: IT Instillation Dose/Concentration: 7mg PM/kg body weight Time to Analysis: DTPA added to some PM samples preinstillation. Instilled with PM. Necropsy 24h postexposure. | Inflammation (LDH, protein, albumin), cytotoxicity (NAG, MPD, TNF- α), and fibrinogen were increased by PM, and were greatest in the coarse PM fraction. Metal-rich PM had greater inflammatory and cytotoxic effects, and increased fibrinogen and vWF and decreased ACE. PAH content influenced greater inflammation (including neutrophils), cytotoxicity, and fibrinogen. Generally, whole PM and coarse PM were more potent than organic extracts and fine PM, respectively. |
| Reference: Ghio et al. (2005, 088272) Species: Rat Gender: Male Strain: N8 b/b Belgrade rats and N8 + lb Belgrade controls | Oil Fly Ash (Southern Research Institute, Birmingham, AL) Particle Size: 1.95 \pm 0.18 μm (MMAD) | Route: IT Instillation Dose/Concentration: 500 μg /rat; 2mg/kg Time to Analysis: 24h | <p>BALF Cells: Homozygous Belgrade with mutation G185R had higher levels of Fe and V 24 h post-exposure. This may demonstrate a decreased ability to remove Fe and V from the lower respiratory tract than heterozygous +lb littermates. This also indicates that DMT1 is normally responsible for at least some Fe and V uptake; thus, a defective DMT1 transports less.</p> <p>BALF Inflammatory/Injury Markers: Increased protein and LDH concentrations in the homozygous strain were observed when compared to control</p> |

| Reference: Ghio et al. (2005, 088275) Species: Rat Gender: Male Strain: Sprague-Dawley Age: 60d Weight: 250-300g | Ferric ammonium citrate (FAC) Vanadyl sulfate (VOSO ₄) Particle Size: NR | Route: IT Instillation Dose/Concentration: 0.5 mL 100 μ m FAC/rat; 0.5 mL 10 μ m VOSO ₄ /rat; 500 μ g oil fly ash; 2 mg/kg Time to Analysis: Single or double exposure with 24 h rest period. Parameters measured 15, 30, 60 min, 24h post-exposure. | DMT1 immunohistochemistry and lung injury: FAC increased and VOSO ₄ decreased –IRE DMT1 staining. Same exposures had no effect on +IRE DMT1. –IRE DMT1 expression in macrophages, airway and alveolar epithelial cells increased with increased Fe exposure. Vanadium nearly eliminated staining except in alveolar macrophages. Increased metal clearance with pre-exposure to FAC. Less metal clearance with pre-exposure to VOSO ₄ . Pre-exposure to iron diminished lung injury whereas pre-exposure to vanadium increased lung injury after oil fly ash instillation. Lung injury measured by concentration of protein and LDH in BAL. |
| Reference: Gilmour et al. (2007, 096433) Species: Mouse Gender: Female Strain: BALB/c Age: 10-12wks Weight: 20-22g | PM - CO, FI, UF (obtained from U.S. Seattle (S), Salt Lake City (SL), South Bronx (SB), Sterling Forest (SF)) SB: included 35% sulfate, 22% gasoline, diesel and brake wear. SF: 48% sulfate. SL: 34% wood combustion and 28% sulfate S: 39% wood combustion and 29% sulfate Residual oil combustion and soil dust less than 5% for all sites. Particle Size: CO: 2.5-10 μ m; FI: \square 2.5 μ m; UF: \square 0.1 μ m | Route: Oropharyngeal Aspiration Dose/Concentration: 25 μ g or 100 μ g PM; 1.25 or 5 mg/kg Time to Analysis: 18h | BALF Inflammatory/Injury Markers: Seattle CO fractions showed no dose-dependent effect on protein concentration. Results for other locations were distinctly higher with 100 μ g dose than 25 μ g and saline doses. SL CO high dose induced the most significant increase. LDH response was weakly dose-related. Only SB showed a statistically significant increase for LDH with the high dose UF. BALF Cells: PMN increased with the high dose of CO samples from SB, SL, S, but not SF. No significant increases from FI were observed, though the high dose induced increased PMN. UF from SL caused a highly variable response. Cytokines: MIP-2 was similar to PMN response. SB CO induced the most significant response. SL UF was highly variable. Particle Characteristics: LPS was higher in S (CO, FI, UF) and SL (CO, FI, UF). Zn levels were highest in SB (CO, FI, UF). Fe was higher in all CO and FI samples with SB CO inducing the highest. |
| Reference: Gilmour et al. (2004, 057420) Species: Mouse Gender: Female Strain: CD1 Age: 8-10wks Weight: 20-25g | Coal Fly Ash MU: Montana Ultrafine MF: Montana Fine MC: Montana Coarse KF: W. Kentucky Fine KC: W. Kentucky Coarse Particle Characteristics: Montana Sulfur 0.83%, Ash 11.72%. Trace amounts of Ba, P, Sr, V, Nb, Cd, Se, Ga, Cu. Depleted in Si, Al, Fe, Mg, Ti. Kentucky Sulfur 3.11%, Ash 8.07% Particle Size: Coarse: > 2.5 μ m; Fine: < 2.5 μ m; Ultrafine: < 0.2 μ m | Route: Oropharyngeal Aspiration Dose/Concentration: 25ug or 100 μ g/mouse Time to Analysis: 18h | BALF Cells: PMN highly increased for MU at both doses. The level was comparable to the positive control. PMN also increased with KF at high dose. Coarse particles caused no significant increase in PMN. Number of macrophages did not change, but NAG increased significantly with MU for both dose levels and with KF and MF at high dose level. BALF Inflammatory/Injury Markers: Total protein and LDH was not significantly elevated. Albumin concentration increased significantly after treatment with the fine high dose of both particle types. Cytokines: MU particles caused a significant increase in TNF- α . MIP-2 increased in all fine and ultrafine PM-instilled animals with the highest in the MU and KF at both doses. IL-6 was detectable only in the BALF of MU and KF with substantial variability. The IL-6 levels were not significant. |

| Reference: Gilmour et al. (2004, 087948) Species: Rat Gender: Male Strain: SH/NQIBR, WKY Age: 12wks Weight: 280-340g | PM (collected from precipitator unit of an oil burning power plant in Boston) Measured Components of PM: S, Zn, Ni, V, Al, Cu, Pb, Fe, Ca, Na, K, Mg, Endotoxin Particle Size: NR | Route: IT Instillation Dose/Concentration: 0.0, 0.83, 3.3, and 8.3 mg/kg in SH rats; 0.0 or 3.3 mg/kg in WKY and SH rats Time to Analysis: 24h | BALF Inflammatory/Injury Markers: LDH activity increased in a dose-related manner; this was observed in SH rats after exposure to 0.83, 3.33 and 8.3 mg/kg PM. SH rats showed greater lung permeability following PM exposure than WKY rats. SH rats showed acute lung inflammatory response after exposure to PM when compared to WKY rats. BALF Cells: No increase in macrophage number was observed in either rat strain following saline or PM exposure at 24 h. Cytokines: MIP2 mRNA expression increased significantly in SH PM exposure group only. No significant differences in TNF- α RNA expression in either WKY, SH rats or control treatment groups were observed. CD14: A significant increase in lung CD14 protein was observed only in SH rats exposed to PM. TLR4: A significant increase in TLR4 protein in SH rats exposed to PM was observed. NF-kB: A significant increase in NF-kB binding protein in the nuclei of SH rats exposed to PM was observed. This effect was not observed in the control of PM-exposed WKY rats. |
| Reference: Gilmour et al. (2004, 054175) Species: Rat Gender: Male Strain: Wistar Age: 12wks | uFCB: Ultrafine carbon black (Printex 90 (Degussa)) CB: (Huber 990, HR. Haefner and Co) Particle Size: uFCB: 14nm; CB: 260nm (primary particle diameter) | Route: Whole-body Inhalation Dose/Concentration: uFCB: 1.66 mg/m ³ fCB: 1.40 mg/m ³ Number concentrations uFCB: 52380 particles/cm ³ fCB: 3800 particles/cm ³ Time to Analysis: Exposed for 7 h. Sacrificed 0, 16 or 48h post-exposure. | BAL Cells: Total number of cells increased significantly in UfCB-exposed rats at 0 and 16 h. Recruitment of cells did not occur in response to CB exposure. PMNs increased significantly in the BALF of uFCB-exposed rats at 16 h. Leukocytes remained unchanged following CB exposure but increased significantly at 0 and 48 h post exposure to uFCB. Cytokine mRNA: A significant increase in BALF MIP-2 mRNA expression was observed at 48 h. No differences in MIP-2 mRNA levels were observed in the whole lung tissue. |
| Reference: Godleski et al. (2002, 156478) Species: Rat Gender: Male Strain: SD Age: NR Weight: 200-250g | CAPs (Boston; Harvard Ambient Particle Concentrator) Particle Size: 0.27 \pm 2.3 μ m (diameter) | Route: Inhalation Dose/Concentration: 73.5-733 μ g/m ³ Time to Analysis: Exposed 5h/d, 3d (consecutive). BAL 24h postexposure | PMNs significantly increased with CAPs exposure and also in relation to CAPs mass, Br, SO ₄ ²⁻ , EC, OC and Pb. An overall increase in pro-inflammatory mediators and decrease in immune enhancer and evidence of vascular endothelial responses occurred with CAPs exposure. |
| Reference: Gottipolu et al. (2009, 190360) Species: Rat Gender: Male Strain: Wistar Kyoto (WKY), SH Age: 14-16wks Weight: NR | DE (30-kW (40hp) 4-cylinder indirect injection Deutz diesel engine) (O ₂ : 20%, CO: 1.3-4.8ppm, NO: <2.5-5.9ppm, NO ₂ : <0.25-1.2ppm, SO ₂ : 0.2-0.3ppm, OC/EC: 0.3 \pm 0.03) Particle Size: Number Median Diameter: Low- 83 \pm 2nm, High- 88.2nm; Volume Median Diameter: Low- 207 \pm 2nm, High- 225 \pm 2nm | Route: Exposure Chamber Dose/Concentration: Low- 507 \pm 4 μ g/m ³ , High- 2201 \pm 14 μ g/m ³ Time to Analysis: Exposed 4h/d, 5d/wk, 4wks. Necropsied 1d postexposure. | DE increased neutrophils in a concentration-dependent manner, and GGT activity at the high dose. Particle-laden macrophages were found in DE-exposed rats. DE dose-dependently inhibited mitochondrial aconitase activity. DE caused 377 genes to be differentially expressed within WKY rats, most of which were downregulated, but none in SH rats. However, WKY rats had an expression pattern shift that mimicked baseline expression of SH rats without DE. These genes regulated compensatory response, matrix metabolism, mitochondrial function, and oxidative stress response. |
| Reference: Gunnison and Chen (2005, 087956) Species: Mouse Gender: Male Strain: DK (ApoE ^{-/-} , LDLr ^{-/-}) Age: 18-20wks | CAPS (Northeastern regional background) Ambient air copollutants measured O ₃ , NO ₂ Particle Size: 389 \pm 2nm | Route: Whole-body Inhalation Dose/Concentration: CAPS = 131 \pm 99 μ g/m ³ including O ₃ = 10 ppb and NO ₂ = 4.4 ppb Time to Analysis: 6h/d, 5d/wk for 4m (5/12/03-9/5/03). Sacrificed 3-4d post exposure. | Microarray Data: 13 genes in the heart tissue and 47 genes in the lung tissue were identified as possibly affected. Strict standards (1.5 fold response, 10 % false discovery rate) resulted in responses by only 1/13 genes (Rex3 - no known heart physiology) in the heart tissue and 0/47 genes in the lung tissue. Using more liberal response (nonstatistical) standards (1.5 fold only) and comparison of each CAPS animal with all 3 control animals (3x3 array) resulted in possible effects on 7 additional genes in the heart tissue and 37 genes in the lung tissue. |

| Reference: Gurgueira et al. (2002, 036535) Species: Rat Gender: Male Strain: Sprague-Dawley Weight: 250-300g | CAPs (Harvard Ambient Particle Concentrator) CB (C198 Fischer Scientific, Pittsburgh, PA USA) Composed of 85.9 ± 0.2% Carbon, 13.0 ± 0.2% O ₂ , 1.17 ± 0.2% Sulfur ROFA (Boston, MA USA oil-fired power plant) Particle Size: CAPs: 1-2.5 μm; CB: < 2.5 μm; ROFA: < 2.5 μm | Route: Whole-body Inhalation Dose/Concentration: 300 ± 60 μg/m ³ Time to Analysis: 1, 3, 5h CAPs Exposure followed by immediate post-exposure analysis. 5h CB, immediate analysis. 30min ROFA, Immediate analysis. | In situ Chemiluminescence(CL): Data show a significant increase in lung and heart CL at 5h. Lung CL increased linearly with time of exposure. Oxidants: CAPs-initiated oxidative stress was not detectable in those rats allowed to recover in room air after the simulated "peak" in particulate air pollution. Rats breathing particle-free filtered air for 3 days had significantly lower levels of oxidants. Exposure to inert CB did not exert oxidant effects on the heart and lung. BALF Inflammatory/Injury Markers: The water content of the lung and heart increased significantly upon exposure to CAPs but not to filtered air and increased as a function of length of exposure. Rats breathing CAPs also showed increases in LDH and CPK as a function of length of exposure. Antioxidant enzymes: Data showed an increase in SOD and catalase activities in both the lung and heart. The pattern of increase was tissue specific. |
| Reference: Hamoir et al. (2003, 096664) Species: Rabbit Strain: New Zealand Age: 12-16 wks Weight: 2.8 ± 0.5kg | PSC: Polystyrene particles, Carboxylate modified, 3 types PSA: Polystyrene particles, Amine modified, 1 type Particle Size: PSC: 24, 110 or 190nm (PSC24, PSC110, PSC190); PSA: 190nm | Route: IT Instillation Dose/Concentration: PSC24: 0.04 or 4 mg/rabbit PSC110, PSC190, PSA190: 4mg/rabbit Time to Analysis: 0, 30, 60, 90, 120min | Capillary Filtration Coefficient: A time-dependent increase correlating to total number of particles/surface area, not particle size, was observed. PSA induced a significant increase in microvascular permeability as compared to PSC. This suggests that the number of particles exposed should be considered an important parameter for measuring air quality rather than total particle surface area. |

| Reference: Happonen et al. (2007, 096630) Species: Mouse Gender: Male Strain: C57BL/6J Weight: 19-30g Age: 10-11wks | PMC (Coarse) PMF (Fine) PMUF (Ultrafine) Collected in 6 European cities: Duisburg, Prague, Amsterdam, Helsinki, Barcelona, Athens Particle Size: PMC: PM _{10.2.5} ; PMF: PM _{2.5-0.2} ; PMUF: PM _{0.2} | Route: IT Instillation Dose/Concentration: PMC: 5.9-29.6 µg/m ³ ; PMF: 8.3-25.2 µg/m ³ ; PMUF: 2.7-6.7 µg/m ³ Dose-response: 1, 3, 10mg/kg Time course: 10 mg/kg Time to Analysis: 1. Dose-Response study: parameters measured 24h post exposure. 2. Time course study: parameters measured 4, 12, 24 h post single exposure (at 10 mg/kg). | <p>Total Cell Numbers: 1. For the dose-response study, all the PMC samples exhibited dose-dependent increases of total cell numbers. The 3 and 10 mg/kg doses of PMC induced statistically significant increases. At 10 mg/kg, only 2/6 samples induced statistically significant increases. No PMUF samples induced effects at any dose. 2. For the time-response study, no increases in cell numbers were shown at 4 h. Though the levels induced by PMC at 24 h were lower than at 12 h, both levels were statistically significant. PMF induced statistically significant increases only at 12 h for 4/6 samples. PMUF induced only 1 significant increase at 12 h; the 24 h time point was not tested.</p> <p>Total Protein/LDH: 1. The lower doses of 1 and 3 mg/kg did not induce significant increases in any of the PM samples, except for PMUF-Athens. All 6 samples of PMC, at 10 mg/kg, induced significant increases. At 10 mg/kg, 4/6 PMF samples induced significant increases. 2. At 4 h, none of the samples increased protein concentration. The PMC samples, excluding Prague, induced significantly higher concentrations at 12 h. At 24 h, only 3/6 PMC samples induced significant increases. Only 2 PMF samples induced significant increases at 12 and 24 h. At 12 h, effects induced by PMUF were minimal and inconsistent; the 24 h time point was not tested.</p> <p>Cytokine: 1. Only PMC induced dose-dependent responses that reached statistical significance at 10 mg/kg. PMF and PMUF induced minimal and inconsistent responses.</p> <p>TNF-α levels: 2. TNF-α levels increased significantly at 4 and 12 h by PMC. At 24 h, TNF-α levels returned to near control levels. PMF, at 4 h, induced statistically significant increases for 3/6 samples and significant increases in 2/6 samples at 12 h. No PMUF samples significantly increased TNF-α levels.</p> <p>IL-6: 2. PMC induced the highest IL-6 levels at 4 h. Levels at 12 and 24 h were reduced with 6/6 and 3/6 samples showing statistically significant increases, respectively. PMF showed a similar trend with 4 h inducing the highest levels that were reduced at 12 and 24 h. Of the PMUF samples, only the Helsinki and Duisburg samples induced statistically significant results at 4 and 12 h. Generally, the PMUF responses were negligible when compared to PMC and PMF.</p> <p>KC production: 2. All PMC samples induced the highest levels at 4 h. At 12 and 24 h, levels were reduced but 4/6 samples induced statistically significant levels. PMF showed a similar trend- the highest levels were induced at 4 h (in 3/6 samples). PMUF at 4 h showed small, though not significant, increases. At 12 h, only 2 samples showed statistically significant differences from the control; the 24 h time point was not tested.</p> |
| Reference: Harder et al. (2005, 087371) Species: Rat Gender: Male Strain: Wistar Kyoto Age: 14-17wks Weight: NR | Carbon UFP Particle Size: Diameter: 37.6±0.7nm | Route: Exposure Chamber Dose/Concentration: 180 µg/m ³ Time to Analysis: Telemeter implanted into peritoneal cavity. 10d recovery. 3d baseline reading. 24h exposure. 3d recovery. | Carbon UFP mildly but significantly elevated HR compared to the control. SDNN was significantly decreased during exposure. UFP induced mild pulmonary inflammation, significantly increased PMN, and increased the total protein and albumin concentrations. Particle-laden macrophages sporadically accumulated in the alveolar region. |

| Reference: Harkema et al. (2004, 056842) Species: Rat Gender: Male Strain: F344, BN Age: 10-12wks Weight: NR | CAPs (Detroit; July-Sept. 2000; Harvard Ambient Fine Particle Concentrator) Particle Size: 2.5 μm (diameter) | Route: Inhalation Exposure Chamber. IT Instillation. Dose/Concentration: 4d concentration: $676 \pm 288 \mu\text{g}/\text{m}^3$, 5d concentration: $313 \pm 119 \mu\text{g}/\text{m}^3$, July concentration: $16\text{-}185 \mu\text{g}/\text{m}^3$, September concentration: $81\text{-}755 \mu\text{g}/\text{m}^3$; IT Instillation- 200 μL (soluble and insoluble) Time to Analysis: F344 rats sensitized to endotoxin, BN rats to OVA. Exposed 10h/d 1, 4, 5d (consecutive). Another group of rats i.t instilled. Both groups killed 24h postexposure. | The retention of PM in the airways was enhanced by allergic sensitization. Recovery of anthropogenic trace elements was greatest for CAPs-exposed rats. Temporal increases in these elements were associated with eosinophil influx, BALF protein content and increased airway mucosubstances. A mild pulmonary neutrophilic inflammation was observed in rats instilled with the insoluble fraction but instillation of total, soluble or insoluble PM _{2.5} in allergic rats did not result in differential effects. |
| Reference: Hiramatsu et al. (2003, 155846) Species: Mouse Gender: Female Strain: BALB/c and C57BL/6 Age: 8wks Weight: 17-22g | DE: generated by 2369-cc diesel engine (Isuzu) at 1050 rpm and 80% load with commercial light oil Particle Size: NR | Route: Whole-body Inhalation Dose/Concentration: DEP: $100 \mu\text{g}/\text{m}^3$ or $3 \text{ mg}/\text{m}^3$; SO ₂ < 0.01ppm; NO ₂ 2.2 ± 0.3 or 15 ± 1.5 ppm; CO 3.5 ± 0.1 or 9.5 ± 0.6 ppm Time to Analysis: 7h/d, 5d/wk for 4 or 12wks, Immediate | BALF Cells: Alveolar macrophages (AMs) increased dose-dependently at 30 and 90d. High DE exposure resulted in bronchus-associated lymphoid tissue (BALT) around DEP-AMs; this was less conspicuous in C57BL/6 than in BALB/c mice. B- and T-cell populations were found in the BALT with no significant differences observed between the strains. Lymphocytes and neutrophils increased time- and dose-dependently with a greater increase in BALB/c than C57BL/6 observed. No eosinophils or basophils were observed. Mac-1-positive cells exposed to high DE levels increased in both strains at 1 month (33.8%) and 3 months (20.3%) vs. low dose group (5.3 and 7% respectively). Cytokines: At 30d, TNF- α , IL-12p40, IL-4 and IL-10 mRNA increased, IL-1b and iNOS decreased. IFN γ increased in BALB/c but decreased in C57BL/c. IL-6 mRNA was not affected. At 90d, IL-4 and IL-10 mRNA similarly increased in C57BL/6 mice exposed to low DE level but decreased at high DE level. |
| Reference: Hollingsworth et al. (2004, 097816) Species: Mouse Gender: Male Strains: C57BL/6 ^{TLR+/+} , C57BL/6 ^{TLR-/-} Age: 8-9 wks | ROFA Particle Size: NR | Route: Oropharyngeal Aspiration Dose/Concentration: 50 μL of $1 \mu\text{g}/\text{mL}$ suspension per mouse Time to Analysis: Parameters measured post single exposure of 6 and 24h. | TLR4-Knockout vs Wild type: There were no observed differences. Methacholine sensitivity: No ROFA effect was observed in wild type or knockout mice. BALF Cells: ROFA increased total cell number. Total number of neutrophils with lavage fluid increased 24 h post-exposure in both strains. |
| Reference: Hutchison et al. (2005, 097750) Species: Rat Gender: Male Strain: Wistar Age: 3m Weight: 250-300g | PM ₁₀ United Kingdom samples collected before (-B), during closure (-C) and reopening of steel plant (-R) PMT = PM total (aqueous sonicate) PMS = PM aqueous supernatant PMI = PM insoluble pellet Particle Size: PM ₁₀ | Route: IT Instillation Dose/Concentration: 112 to 180 μg PM in 500 μL ; 0.44-0.72 mg/kg Time to Analysis: 18h | BALF Cells: PMT-R neutrophil cell number and percentage were significantly higher than PMT-C or control. PMS-R and PMI-R were also higher than their respective controls. The neutrophil cell numbers induced by PMI-R were greater than PMI-C and the control. Total cell count unchanged. BALF Inflammatory/Injury Markers: Only albumin increased after PMT-R. Upon exposure, total protein and LDH did not increase. Cytokine mRNA expression: Only PMT-R increased IL-1 β mRNA expression. No effects on TNF- α and TGF β expression levels were observed. IL-6, MIP2, and GM-CSF mRNA was not detected in BAL cell extracts from either the control or treated groups. |
| Reference: Inoue et al. (2006, 097815) Species: Mouse Gender: Male Strains: C3H/HeJ (TLR-4 point mutant) and C3H/HeN (Control) Age: 6 wks | DEP (derived from 4 cyl, 2.74l light duty diesel engine) Particle Size: NR | Route: IT Instillation Dose/Concentration: 12mg/kg of bw Time to Analysis: 24h | Airway Inflammation: DEP induced an increase in total cells ($P < 0.01$), neutrophils ($P < 0.01$) and mononuclear cells in BALF. TLR4 knockout mice (C3H/HeJ) showed a much lower response. Cytokines: DEP induced a massive increase in MIP-1 α , IL-1 β and KC. However, levels of MIP-1 α were significantly less in the knockout than the wild type while levels of IL-1 β and KC were significantly higher in knockouts than the wild type. Hematology: DEP increased plasma fibrinogen in both strains but with a greater increase in the knockout mice than the wild type. |

| Reference: Inoue et al. (2006) Species: Mouse Gender: Male Strain: NC/Nga Age: 10wks | DEP (derived from 4 cyl, 2.74l light duty diesel) Particle Size: NR | Route: IT Instillation Dose/Concentration: 100 μ g/mouse Time to Analysis: 1/wk for 6wks. Parameters measured 24h after last administration | BALF Cells: DEP significantly increased total cells, neutrophils and mononuclear cells but did not induce an effect on eosinophils. Cytokines: DEP increased IL-4, KC and MIP-1. The increase in IL-5 was not statistically significant. |
| Reference: Ishihara et al. (2003, 096404) Species: Rat Gender: Male Strain: Wistar Age: 5wks | DE (from 2 engines, produced on site) -L = low level DE -M = medium level -MG = DE w/o particulates -HR = high level Measured Components: NO ₂ , SO ₄ , SO ₂ , CO, CO ₂ , NO _x , NO, HTHC, HCHO, O ₂ Particle Size: L: 0.33 -0.50 μ m M: 0.35 - 0.40 μ m HR: 0.42 - 0.45 μ m | Route: Whole-body Inhalation Dose/Concentration: L: 0.18 - 0.21 mg/m ³ M: 0.92- 1.18 mg/m ³ MG: 0.01 mg/m ³ HR: 2.57 - 2.94 mg/m ³ Time to Analysis: 16h/d, 6d/wk, for 6, 12, 18 & 24 m. Parameters measured immediately following last exposure. | Morbidity and Mortality: Weight gain in HR group was less than other groups at 18 and 24 mo. This indicates a significant difference between the HR and C group. Mortality during the study was frequent. C group experienced an 8% mortality rate, L group 12%, M group 15%, MG group 12% and HR group 23%. BALF Inflammatory/Injury Markers: Significant differences were seen among groups with respect to number of total cells and percentages of cell differential, total protein, fucose, sialic acid, phospholipid and prostoglandin E2. Total protein increase was observed in both M and HR dose groups with the HR group increasing time-dependently. BALF Cells: The HR group showed a significant increase in total cell count from 6 to 18mo. The percentage of PMN increased at 6mo in M, MG and HR group. M group lymphocytes significantly increased at 6, 12, and 24mo of exposure. Macrophages decreased at 6mo for the M and HR groups. Mucus and Surfactant: The HR group showed a significant increase from 12 to 18mo. |
| Reference: Jones, HR.A. Hamacher, K. Clark, J.C. 2005 Species: Rabbit Strain: New Zealand Weight: 2.5- 3.5kg | ASP: Amorphous silica particles (Hypersil) MCSP: Microcrystalline silica particles Particle Size: ASP: 5 μ m; MCSP: 5 μ m | Route: Intrapulmonary Instillation (Right upper lobe of lung) Dose/Concentration: 50mg in 0.5mL saline Time to Analysis: Parameters measured at varying times from 6h to 91d post treatment. | MCSP: At 6h, neutrophils increased. Macrophages increased 3 fold. At 60h, neutrophils were pyknotic and the lungs displayed a thickened interstitium containing silica particles. At 5d, collagen deposition appeared. At 8d, fibroblastic activity and necrosis were observed. At 15d, aggregation of silica particles and necrotic debris were apparent. At 8 wks, fibroblasts were still present. At 13 wks, active scarring and raised neutrophil macrophage counts were still present. ASP: At 15h, neutrophils increased. Macrophages tripled and remained increased for 3wks. At 4d, macrophages bore particles. At 13d, neutrophils decreased significantly. By 25d, silica spheres were gradually removed from lungs. PET Scanning: 18F-fluoroproline showed increased activity beginning at 14d and peaking at 41-54d (left lung control vs right lung challenged). Microautoradiography: 3h-proline at 13 weeks showed radiolabel localization to fibroblasts in the challenged lung |

| Reference: Kato and Kagawa (2003, 089563) Species: Rat Gender: Male Strain: Jcl Wistar Age: 5wks | Roadside air (Prefectural Tokyo-Danishi-Yokohama highway, Yokohama-Haneda Airport Metropolitan expressway and Satsukibashi-Mizuecho city road, Japan) Particle Size: NR | Route: Whole-body Inhalation Dose/Concentration: Exposed group: 55.7 ppb NO ₂ , 62.7 µg/m ³ PM; Control group: 5.1 ppb NO ₂ , 14.3 µg/m ³ PM Time to Analysis: Exposed for 24, 48, 60 wks. Parameters measured immediately following exposure. | Respiratory tissue: Post 24wks, the lung surface was light gray with some BC particle deposits. Post 48-60wks, however, the surface was scattered with particle deposits in addition to its light gray color. Airway changes: After 60 wks, no remarkable changes seen in the epithelium. The structure of the airways remained normal. Cells: No proliferation or ectopic growth of goblet cells were noted. Mast cells increased in epithelial intercellular space. No mast cell degranulation was observed. Lysosomes increased in ciliated cells post 48wks. Clara cells were unaffected. Lymph nodes: Deposition of carbon particles were noted in the trachea and bronchiole-associated lymph nodes post 24wks. Alveolar changes: No changes in morphology of broncho-alveolar junctions were noted. Anthracosis observed within alveolar walls and pleura post 24wks and became progressively marked with increased exposure. No change in the number of alveolar holes between exposure and control groups were observed. |
| Reference: Kato, T. Yashiro, T. Murata, Y. 2003 Species: Rat Gender: Male Strain: Sprague-Dawley Age: 7wks Weight: 190-220g | Polystyrene latex suspension of latex beads (Japan Synthetic Rubber Co.), uncoated or coated with lecithin Particle Size: 240nm | Route: IT Instillation with nebulizer Dose/Concentration: 5ml of 0.2% suspension administered over 20 min at flow rate of 0.25ml/min Time to Analysis: Exposed for 20min. Parameters measured 30min following treatment. | Alveolar Macrophages: Following treatment, AMs appeared undamaged. AMs ingested more uncoated than coated beads, but both were ingested. Ingestion of beads differed as coated beads were engulfed individually while uncoated beads were engulfed individually or in aggregates. Epithelial Cells: Type I cells incorporated coated beads within a layer of cytoplasm. Type II cells incorporated beads in lamellar bodies. Uncoated beads were not incorporated. Other: Neither type of beads were incorporated into endothelial cells, fibroblasts or interstitium of alveolar wall Monocytes: Only the coated beads were incorporated by the monocytes. They were found inside and outside phagosomes and lysosomes of monocytes. PMNs did not incorporate any beads. |
| Reference: Kleinman et al. (2003, 053535) Species: Rat Gender: NR Strain: F344n-NIA Age: 22-24m | O ₃ CCL: O ₃ + Ammonium bisulfate (ABS) + Elemental Carbon (EC) CCH: O ₃ + ABS + EC Purified Air (control) Particle Size: CCL: 0.30 ± 2.5 µm CCH: 0.29 ± 2.3 µm | Route: Nose-only Inhalation Dose/Concentration: O ₃ : 0.2ppm CCL: 50 µg/m ³ EC + 70 µg/m ³ ABS + 0.2 ppm O ₃ CCH: 100 µg/m ³ EC + 140 µg/m ³ ABS + 0.2 ppm O ₃ Time to Analysis: 4h/d, 3 consecutive d/wk for 4wks | DNA Replication: O ₃ caused a slight effect of 20-40% increase. CCL and CCH caused between 250 - 340% increase for interstitial and epithelial cells. CCL induced greater reactions than the high dose. BALF Inflammatory/Injury Markers: Total protein, mucus glycoprotein and albumin were somewhat elevated in all exposure groups but only reached statistically significance for CCL and protein (very high variability). CCL and CCH both depressed Fc receptor side binding. No effect for O ₃ was observed. BALF Cells: CCL and CCH induced macrophage respiratory burst activity. The effect induced by O ₃ was not significant. |
| Reference: Kleinman and Phalen (2006, 088596) Species: Rat Gender: Male Strain: Sprague-Dawley Age: 6 wks Weight: 200g | LO3: Low O ₃ HO3: High O ₃ LS: Low H ₂ SO ₄ HS: High H ₂ SO ₄ LOLS: Low O ₃ + Low H ₂ SO ₄ LOHS: Low O ₃ + High H ₂ SO ₄ HOLLS: High O ₃ + low H ₂ SO ₄ HOHS: High O ₃ + high H ₂ SO ₄ Particle Size: LS = 0.23 µm ± 2.3 HS = 0.28 µm ± 2.1 LOLS = 0.23 µm ± 2.3 LOHS = 0.28 µm ± 2.1 HOLLS = 0.23 µm ± 2.3 HOHS = 0.28 µm ± 2.1 | Route: Nose-only Inhalation Dose/Concentration: LO3 = 0.30ppm HO3 = 0.61ppm LS = 0.48mg/m ³ HS = 1.00mg/m ³ LOLS = 0.31ppm + 0.41mg/m ³ LOHS = 0.31ppm + 1.04mg/m ³ HOLLS = 0.60ppm + 0.52mg/m ³ HOHS = 0.60ppm + 0.86mg/m ³ Time to Analysis: Exposed for 4h. Parameters measured 42h post-exposure. | Inflammatory Lesions in Lung Parenchyma: Neither Type 1 or 2 lung lesions were affected by sulfuric acid alone. HO3 doubled Type 1 lesions and increased Type 2 lesions 25-fold. Additions of H ₂ SO ₄ to O ₃ appeared to have a dose-dependent protective effect for both types of lesions. DNA Synthesis in Nasal, Tracheal and Lung Tissue: Increased DNA synthesis was observed at all high O ₃ exposures but was not affected by coexposure to H ₂ SO ₄ . Macrophage FcR binding: No effects were observed (no data for LO3 and HO3). Macrophage Phagocytosis: All levels of exposure (no data for LO3 and HO3) decreased phagocytosis. |

| Reference: Kodavanti et al. (2005, 087946) Species: Rat Gender: Male Strain: WKY and SH/NCrIBR Age: 11-14wks | CAPs (EPA, NC) Measured components included Al, Be, Ba, Co, Cu, Zn, Pb, Mn, Ni, Ag, Ti, As. Particle Size: 1d: 1.07-1.19 μm ; 2d: 1.27-1.48 μm | Route: Whole-body Inhalation Dose/Concentration: 1d study: 1138-1765 $\mu\text{g}/\text{m}^3$ 2d study: 144-2758 $\mu\text{g}/\text{m}^3$ Time to Analysis: 4hr (SH only); 4hr/day, 2d (WKY and SH) Post-exposure: 1d: 3h except study #4, 18-20h; 2d: 18-20h | Breathing Parameters: In a paired analysis of control SH and treated SH, treated SH showed an increase in expiratory and inspiratory time due to CAPs. The treated and control groups of WKY rats did not show significant differences. BALF Cells: In the 2d study, WKY rats showed decreases in total cells; this decrease was associated with decreased macrophages. WKY showed an increase in neutrophils. BALF Inflammatory/Injury Markers: Total protein and albumin in WKY rats decreased whereas SH rats maintained the same approximate level. LDH activity lowered slightly in both strains. Cell Membrane Integrity: SH rats showed increased GGT (membrane bound enzyme) activity and plasma fibrinogen for 5/7 exposures but these increases did not appear to be dose-dependent. Cytokines: Levels were undetermined in SH rats. WKY showed slight increases in IL-6, TNF- α , and MIP-2 but these increases were not statistically significant. |
| Reference: Kooter et al. (2006, 097547) Species: Rat Gender: Male Strain: SH Age: 12-14wks | CAP-F = fine (Site I) CAP-UF = fine + ultrafine (Site II) (Netherlands) Some measured Components: Ammonium, nitrate, sulphate ions: $56 \pm 16\%$ CAP-F mass, $17 \pm 6\%$ CAP-UF mass Particle Size: 0.15 < CAP-F < 2.5 0.65-0.75 μm CAP-UF < 2.5 0.58-1.41 μm | Route: Nose-only Inhalation Dose/Concentration: CAP-F 399- 3613 $\mu\text{g}/\text{m}^3$ CAP-UF 269-556 $\mu\text{g}/\text{m}^3$ Time to Analysis: 6h/d for 2d consecutive, 18h | BALF Inflammatory/Injury Markers: Based on unchanged levels of LDH and ALP, no cytotoxicity was noted. No significant change in the levels of total cells were observed. MDA (malondialdehyde) decreased with CAP-UF. Ho-1 increased with CAP-UF and CAP-F. Cytokines: CC16 decreased at 457 $\mu\text{g}/\text{m}^3$ of CAP-F and increased at 3613 $\mu\text{g}/\text{m}^3$ of CAP-F. Hematology: WBC and lymphocytes decreased with both CAP-F and CAP-UF. MPV and MPC (mean platelet volume and component) increased with CAP-UF. BALF Cells: A decrease in absolute neutrophils as well as percentages of reticulocytes and percentages of neutrophils were observed with CAP-F. Increased percentages of lymphocytes were observed with CAP-F. Pathology. No changes were observed. |
| Reference: Kumar et al. (2004, 096655) Species: Rat Gender: Male Strain: Wistar Weight: 150 \pm 20g | Fly Ash (Obra Thermal power Station, India) Particle Size: PM < 5 μm (90%) | Route: Whole-body Inhalation Dose/Concentration: 14.4 \pm 1.77 mg/m ³ (fluid bed generator) Time to Analysis: 4h/d for 28d. Parameters measured immediately following last exposure. | Lung Weight: Lung body weight increased 25.58% relative to controls. Total body weight slightly decreased in the treated group. BALF Inflammatory/Injury Markers: LDH, GGT, ALP and lavagable protein increased by 140, 450, 160 and 50%, respectively. BALF Cells: Only eosinophils(%) increased 95% over controls. Congestion and focal infiltration of monocytes in alveolar area was seen. Fly ash laden macrophages in alveoli combined with hypertrophy of epithelial lining cells was observed. |
| Reference: Lei et al. (2004, 087999) Species: Rat Gender: Male Strain: Sprague-Dawley Weight: 318 \pm 8g | CAPs (Yaipei, Taiwan) Particle Size: PM: 0.01- 2.5 μm | Reference: Nose-only Inhalation Dose/Concentration: 371 \pm 208 $\mu\text{g}/\text{m}^3$ Time to Analysis: 6h/d for 3d, 5h post-exposure pulmonary function. 2d post-exposure for BALF collection Pulmonary hypertension induced 2wks pre-exposure | Respiratory Effects: Decreased respiratory frequency and increased tidal volume for both experimental and control groups were observed. However, only the experimental group levels were statistically significant. There was an increase in airway responsiveness (Penh/methacholine) for CAPs group when compared to the control. BALF Cells: A massive increase in total cell number and percent neutrophils was observed. There were no changes in percent macrophages, lymphocytes and eosinophils. BALF Inflammatory/Injury Markers: Total protein and LDH increased in the CAPs group. Cytokines: TNF- α and IL-6 were not affected. |

| Reference: Lei et al. (2004, 087884) Species: Rat Gender: Male Strain: Sprague-Dawley Weight: 300-350g | CAPs from Asian dust storm (Taiwan) Measured Components: Si, Al, S, Ca, K, Mg, Fe, As, Ni, W, V, organic carbon, elemental carbon, SO ₂ , NO ₂ , nitrate, sulfate Particle Size: PM: 0.01- 2.5 μm | Route: Nose-only Inhalation Dose/Concentration: 315.6 μg/m ³ (Low) or 684.5 μg/m ³ (High) Time to Analysis: Low: Exposed for 6h. Sacrificed 36h post-exposure High: Exposed for 4.5h. Sacrificed 36h post-exposure Pulmonary hypertension induced 2wk pre-exposure | Hematology: PM induced a dose-dependent increase in WBCs. No change was seen in RBCs. Platelet results were highly variable. BALF Cells: PM induced dose-dependent increases in total cells and percentage of neutrophils. No change in macrophages, lymphocytes or eosinophils occurred. Basophils were highly variable. BALF Inflammatory/Injury Markers: Dose-dependent increases were observed for total protein and LDH. Cytokines: IL-6 increased dose-dependently. (control: 33.5 ± 7.5, LOW 165.1 ± 117.2, 273.6 ± 62.8 pg/mL) |
| Reference: Li et al. (2007, 155929) Species: Mouse Gender: Female Strain: BALB/c, C57BL/6 Age: 9wks Weight: NR | DEP (2369-cc diesel engine manufactured by Isuzu Motor, operated at 1050 rpm, 80% load, commercial light oil) Particle Size: NR | Route: Exposure Chamber Dose/Concentration: DEP: 103.1 ± 9.2 μg/m ³ , CO: 3.5 ± 0.1ppm, NO ₂ : 2.2 ± 0.3ppm, SO ₂ : < 0.01ppm Time to Analysis: Protocol 1: Exposed 7h/d, 5d/wk. Sacrificed at day 0, week 1, 4, 8. Protocol 2: DE alone or DE + NAC 7h/d, 1-5d. | Airway hyperresponsiveness: Penh values increased in BALB/c mice compared to the control at day 0, but no significant changes occurred after this time. Penh values increased in C57BL/6 mice at 1wk compared to the control but returned to control levels at 8wks. BALF: Compared to the other strain, the total number of cells and macrophages increased significantly at 1wk in C57BL/6 mice and at 8wks in BALB/c mice. Neutrophils, lymphocytes, MCP-1, IL-12, IL-10, IL-4, IL-13 increased significantly for both strains. No eosinophils were found. IL-1β and IFN-γ increased significantly in BALB/c mice compared to C57BL/6 mice. HO-1 mRNA and protein: HO-1 mRNA was more marked in BALB/c mice at 1wk and C57BL/6 mice at 4 and 8wks. HO-1 protein percentage changes from the control were greater in BALB/c mice at 1wk and C57BL/6 mice at 8wks. NAC: NAC inhibited the increased Penh values, total number of cells and macrophages in C57BL/6 mice at 1wk and neutrophils and lymphocytes in both strains. |
| Reference: Liu et al. (2008, 156709) Species: Mouse Gender: Female Strain: BALB/c Age: 11wks Weight: NR | DEP (5500-watt single-cylinder diesel engine generator (Yanmar, Model YDG 5500E), 406 cc displacement air-cooled engine, Number 2 Diesel Certification Fuel, 40 weight motor oil) Particle Size: ~ 0.1 μm (MMAD) | Route: Intranasal Exposure Dose/Concentration: Average particle concentration: 1.28mg/m ³ Time to Analysis: Four groups: saline + air control, saline + DEP, <i>A. fumigatus</i> + air, <i>A. fumigatus</i> + DEP. <i>A. fumigatus</i> exposure every 4d for 6 doses. DEP exposure 5h/d for 3wks concurrent with <i>A. fumigatus</i> exposure. | <i>A. fumigatus</i> + DEP increased IgE, the mean BAL eosinophil percentage, goblet cell hyperplasia, and eosinophilic and mononuclear cell inflammatory infiltrate around the airways and blood vessels compared to the <i>A. fumigatus</i> or DEP treatments. <i>A. fumigatus</i> + DEP also caused methylation at the IFN-γ promoter sites CpG ⁻⁵³ , CpG ⁻⁴⁵ , and CpG ⁻²⁰⁵ . |
| Reference: Lopes et al. | Reference: Mangum et al. (2004, 097326) Species: Rat Gender: Female Strain: CDF (F344)/CrIBR Age: 7wks | TiO ₂ pigment grade (DuPont) Particle Size: NR | Route: Whole-body Inhalation Dose/Concentration: 10, 50 or 250mg/m ³ Time to Analysis: 6h/d x 5d/wk for 13wks. Parameters measured 0, 4, 13, 26, 52 wks post-exposure. | OPN (osteopontin) Expression: At 0 wks, OPN mRNA expression exhibited a dose-dependent increase. Low dose induced a 2-fold increase while the high dose induced an almost 100 -fold increase. At 4 wks, the mid-dose and high-dose elevated OPN mRNA levels. At 13wks, the high dose elevated OPN mRNA levels.No significant elevation with mid dose level was observed. At 26wks, the mid and high dose induced elevated OPN mRNA levels. At 52wks, rats in the low, mid and high dose groups all indicated elevated levels of OPN mRNA. Specifically, the low, mid and high doses induced a 3-fold increase, 7-fold increase and 400-fold increase, respectively. OPN Protein in BALF: Data was not reported at 0 and 4 wks. At 13 wks, protein increased 9-fold (~ 800 pg/mL OPN) at mid dose and 100 -fold (~ 8000 pg/mL OPn) at high dose. At 26 wks, the mid and high dose groups remained elevated. At 52 wks, protein increased by 2.5 fold in low dose, 7-fold in mid dose and 166-fold in high dose group. Histopathology: At 52wks, slight OPN immunoreactivity was observed in control and low dose group (immunostaining mostly limited to intraalveolar MACS).Trichrome-stained lung sections from control and low dose groups showed no increase in collagen. Rats exposed to mid or high dose groups showed areas of lesions. |
| Reference: Martin et al. (2007, 096366) Species: Mouse Gender: Male Strain: BALB/c Age: 1-2 mo | UAP-BA: Urban Air particles (Buenos Aires, Argentina) Particle Size: < 2.5µm | Route: Intranasal Installation Dose/Concentration: 0.17 mg/kg bw Time to Analysis: 3xday, 3d/wk, 2d apart (1, 4, 7d). Parameters measured 1h post-exposure. | Particle Characteristics: 3 types, ultrafines < 0.2µm (inorganics ND), bunched agglomerates of ultrafines and < 40µm with aluminum silicates, ions and trace metals. Morphometry: Induced focal inflammatory lesions. Accumulation of refractile material in upper and lower respiratory tract. PM in phagocytes of bronchiolar lumen and alveolar space. No evidence of fibrosis and/or collagen changes. BALF Cells: Increased amount of phagocytes in alveolar area, reducing airspace percentage (control 52.9% ± 1.39, UAP-BA 24.7% ± 2.87). Increased number of PAS positive cells. |
| Reference: Mauad et al. | Reference: McQueen et al. (2007, 096266) Species: Rat Gender: Male Strain: Wistar Weight: 228-500g | DEP: SRM 2975 (NIST) Particle Size: NR | Route: IT Instillation Dose/Concentration: 0.5 mL/rat of 1 mg/mL; 1-2.2 mg/kg Time to Analysis: Single exposure, sacrificed 8h post-exposure. Pre-exposure: Vagotomy (sectioning of vagus nerve) or Atropine 1mg/kg i.p. administered 30 min prior, 2 and 4h post. | BALF Cells: A 9-fold increase in neutrophils with high individual variability in response was observed. Bilateral vagotomy prior to DEP reduced neutrophil increase to 3 fold. Vagotomy with saline instillation had no effect. Atropine reduced neutrophils to levels similar to saline response. No differences were observed between DEP response in anesthetized when compared to conscious animals. Macrophages, eosinophils and lymphocytes remain unchanged. Respiratory Response: RMV increased post DEP. Vagotomy reduced response by one-third. Atropine pre-treatment did not have effect. Cardiovascular Response: Blood pressure and heart rate were unaffected. Average arterial O ₂ increased after DEP, but not when compared for each animal. CO ₂ and pH were not affected |
| Reference: Medeiros et al. (2004, 096012) Species: Mouse Gender: Male Strain: BALB/c Age: 60d Weight: 20-30g | CP: Carbon particles PSA: ROFA (solid waste incinerator hospital Sao Paulo, Brazil) PSB: electric precipitator, steel plant, Brazil) PSA/PSB Characteristics: Generally, PSB had greater component concentrations than PSA: Br (100+x), Cr (3x), Fe (10+x), Mn (2x), Rb (60+x), Se (7x), Zn (4x). PMA > PMB: Ce (3x), Co (10+x), La (100x), Sb (15x), V (50x). Particle Size: CP: 1.7 ± 2.5 µm (78% < 2.5 µm) PMA: 1.2 ± 2.2 µm (98% < 2.5 µm) PMB: 1.2 ± 2.2 µm (98% < 2.5 µm) | Reference: Intranasal Instillation Dose/Concentration: CP: 10 µg/mouse; 0.5mg/kg PSA: 0.1, 1 or 10 µg/mouse; 0.005, 0.05, 0.5 mg/kg PSB: 0.1, 1 or 10 µg/mouse; 0.005, 0.05, 0.5 mg/kg Time to Analysis: Single, 24h | Hematology: PSA and PSB decreased leukocyte count (all 3 doses) and platelet count (2 high doses). No effect on hemoglobin, erythrocytes and reticulocytes was observed. Fibrinogen levels increased for both PSB and PSA with PSB seeing a higher increase. None of the effects were dose-dependent. Bone Marrow: Erythroblasts increased for PSA at all dose levels and PSB at mid and high dose levels (high variability). BALF Cells: No change in BAL cell count was seen. Quantitative cellular counts increased for perivascular area for both groups at all dose levels. Inflammatory cells in alveolar septum area only increased for PSA. |
| Reference: Mutlu et al. (2006, 155994) Species: Mouse Strain: C57BL/6 Age: 6-8wks Weight: 20-25g | PM ₁₀ Collected by baghouse from Dusseldorf, Germany Particle Size: NR | Route: IT Instillation Dose/Concentration: 100 ng/mouse; 1 µg/mouse; 10 µg/mouse; 100 µg/mouse Time to Analysis: 1-7d | Alveolar Fluid Clearance: At 100 µg/mouse, decreased clearance peaked at 24 h and recovered at 7d. Histology: Evidence of mild lung injury at doses of 100 µg/mouse or more was seen. BALF Cells: Significant increase in total cell number was observed. Neutrophils increased but this was not statistically significant. Wet/Dry Ratio: Exposure did not induce any effects. Na, K-ATPase: At 100µg/mouse, decreased activity of Na, K-ATPase in basolateral membranes was observed. |
| Reference: Nadziejko, et al. (2002, 087460) Species: Rat Gender: Male Strain: SHR (spontaneously hypertensive rats) Age: 16wks | CAPs: produced at Tuxedo, NY laboratory using centrifugal aerosol concentrator FA: Fine Particle Sulfuric Acid Aerosol UFA: Ultra-Fine Particle Sulfuric Acid Aerosol Particle Size: CAPs: PM _{2.5} ; FA: 180nm; UFA: 50-75nm | Route: Nose-only Inhalation (implanted blood pressure transmitters) Dose/Concentration: CAPS 80, 66 µg/m ³ ; avg 73 µg/m ³ FA 299, 280, 119, 203 µg/m ³ ; avg 225 µg/m ³ UFA 140, 565, 416, 750 µg/m ³ ; avg 468 µg/m ³ Time to Analysis: 10 exposures of 4h each, each exposure at least 1 wk apart. (2 exposures to CAPs, 4 to FA and 4 to UFA) | Respiratory rate: CAPs decreased the respiratory rate as did FA at all dose levels. However, the FA-induced respiratory rate was not statistically significant unless the data was combined. UFA increased this rate significantly. Heart Rate: CAPs depressed the heart rate significantly during exposures (data only significant when combined) but returned to normal post-exposure. FA induced a decrease as well with continuation 7h post-exposure. UFA increased heart rate. Diastolic Blood Pressure: Caps and FA induced a decrease but this was not statistically significant. UFA induced a slight increase. |

| Reference: Nemmar et al. (2007, 156800) Species: Rat Gender: Male Strain: Wistar Kyoto Age: 16wks Weight: 424 ± 8g | DEP: SRM 2975 Particle Size: < 1µm | Route: Intravenous Injection Dose/Concentration: 0.02, 0.1 or 0.5 mg/kg Time to Analysis: single, 24h | Cardiovascular: DEP depressed blood pressure at all doses approximately equally. DEP depressed heart rate at all doses equally. Hematology: No effect on number of platelets, granulocytes, monocytes, lymphocytes or RBC s. Tail bleeding time (associated with platelet activity) decreased at doses of 0.02 and 0.5mg/kg. BALF Cells: Marked cellular influx at all dose levels Was observed. Macrophages increased at the high dose, but this was not statistically significant. PMN increased significantly at all dose levels. Wet/Dry Ratio: All dose levels induced increases. |
| Reference: Nemmar et al. (2003, 087931) Species: Hamster Gender: Male and Female Weight: 100-110g | PS: Polystyrene particles PSC: Polystyrene particles, Carboxylate modified PSA: Polystyrene particles, Amine modified Particle Size: PS, PSC, PSA-60: 60nm; PSA-400: 400nm | Route: IT Instillation Dose/Concentration: 5, 50 or 500 µg/animal; 0.05, 0.5, 5mg/kg Time to Analysis: Single, 10min post-exposure Rose Bengal administered to induce thrombosis, immediate study thereafter | Thrombosis: Only PSA-60 at 50 and 500 levels enhanced thrombus formation but not in a dose-dependent manner. At 500 µg, PSA-60 showed evidence of pulmonary thrombosis. No effect with PSA-400 was seen. BALF Cells: Both PSA-60 and PSA-400 (PSA-60 > PSA-400) induced a massive influx of PMNs. PSA-60 effect may exhibit some dose-dependency. BALF Inflammatory/Injury Markers: Small increases in total protein were seen at 500 µg level for both PSA-60 and PSA-400. LDH was increased at all PSA-60 levels but not for 500ug PSA-400. Histamine increased for all PSA-60 levels and PSA-400 but due to high variability only the effect at 500 µg PSA-60 was statistically significant. Hematology: PSA-60 and PSA-400 had an effect on platelet closure time at very low concentrations: 3 and 9 µg/l respectively and plateaued thereafter. |
| Reference: Nemmar et al. (2003, 097487) Species: Hamster Gender: NR Weight: 100-110g | DEP: SRM 1650 Particle Size: NR | Route: IT Instillation Dose/Concentration: 50 µg/animal Time to Analysis: Single exposure, parameters measured 1, 3, 6 or 24h post exposure. | BALF Cells: DEP led to a significant PMN flux at 1 h (13% of total cell number), 6 h (22%) and 24 h (37%). Thrombosis: DEP induced a significant increase in the cumulative mass of in vivo generated thrombus when compared to control subjects. Hematology: No decrease in platelet count was observed. Consistent (non time-dependent) decrease in closure time signified increased platelet activation for DEP-exposed groups. Histamine: Concentrations in BALF were consistently elevated starting at 1 h. Plasma histamine did not increase until 6 h. Pretreatment with histamine receptor antagonist: A major decrease in DEP induced PMN infiltration was seen. Thrombogenicity was decreased after 6h as was closure time shortening. No effect on histamine in BALF or plasma was observed. |
| Reference: Nurkiewicz et al. (2009, 191961) Species: Rat Gender: Male Strain: SD Age: 7-8wks Weight: NR | Fine TiO ₂ (Sigma-Aldrich- (titanium (IV) oxide, 224227, St. Louis, MO) (~ 99% rutile) TiO ₂ nanoparticles (DeGussa-Aeroxide TiO ₂ P25, Parsippany, NJ) (80% anatase, 20% rutile) Particle Size: Fine TiO ₂ - Primary size: < 5 µm, MMAD: 402nm, CMD: 710nm; Nano-TiO ₂ - Primary size: 21nm, MMAD: 138nm, CMD: 100nm | Route: Aerosol Inhalation Dose/Concentration: 1.5-16mg/m ³ Time to Analysis: Acclimated 5d. Exposed 240-720min. Anesthetized 24h postexposure. Intravital microscopy, NO measurement, microvascular oxidative stress measurement, nitrotyrosine staining. | Arteriolar Dilation: Nano-TiO ₂ significantly impaired endothelium-dependent arteriolar dilation. Equivalent levels of arteriolar dysfunction were found in fine and nano-TiO ₂ . Arteriolar dilation in response to abluminal microiontophoretic application of SNP was not different from the controls or between the exposure groups. Arteriolar dilation was partially restored by radical scavenging with TEMPOL and catalase, NADPH oxidase with apocynin, and MPO inhibition with ABAH. Microcirculation: ROS increased in both groups. Nano-TiO ₂ significantly increased the area of tissue containing nitrotyrosine in the lung and spinotrapezius microcirculation. NO: Fine and nano-TiO ₂ significantly and dose-dependently decreased stimulated NO production in isolated microvessels. NO production was increased by radical scavenging with TEMPOL and catalase or NADPH oxidase with apocynin, and was largest in the fine TiO ₂ group. |

| Reference: Pereira et al. (2007, 156019) Species: Rat Gender: Male Strain: Wistar Age: 3m | Ambient Particles (Porto Alegre, Brazil) Particle Size: < 10µm | Route: Whole-body Inhalation Dose/Concentration: P-6: 34, 22 or 225 µg/m ³ P-20: 139 or 112 µg/m ³ P-I: 99 µg/m ³ Time to Analysis: P-6: single/continuous for 6h P-20: single/continuous for 20h P-I: intermittent (5h) periods per day for 4d consecutively Parameters measured 0 or 24 h post-exposure | BALF Inflammatory/Injury Markers: An increase in lipid peroxidation was statistically significant only for the 20 h continuously exposed group. Leukocytes also increased at P-20. No change at P-6. Total protein remained unaffected at all dose levels. Wet to Dry Ratio (0h): No effect was observed. |
| Reference: Pinkerton et al. (2004, 087465) Species: Rat Gender: Female (pregnant), Offspring- NR Strain: SD Age: 10d (pups), Pregnant females- 10-14d of gestation Weight: NR | PM (Fe and soot from combustion of acetylene and ethylene in a laminar diffusion flame system) Particle Size: Median diameter: 72-74nm; size range: 10-50nm | Route: Inhalation Dose/Concentration: Mean mass concentration: 243±34 µg/m ³ ; Average Fe concentration: 96 µg/m ³ Time to Analysis: Exposed 10d postnatal age, 6h/d, 3d (consecutive). Bromodeoxyuridine injected 2h before necropsy. | A significant reduction of cell proliferation occurred only within the proximal alveolar region of exposed animals compared to controls. There were no significant differences between the groups for alveolar formation and separation within the proximal alveolar region. |
| Reference: Pinkerton et al. (2002, 087645) Species: Rat Gender: Male, Female Strain: SD Age: 11-13wks (adult male), 10-12d (neonatal) Weight: NR | PM (Fe, Soot) (ethylene, iron pentacarbonyl, acetylene combined; Fe ₂ O ₃ ; soot: 60% EC, 40% OC) (CO, NO _x) Particle Size: Fe (diameter)- 40nm; Soot (primary particles, diameter)- 20-40nm | Route: Whole-body Exposure Dose/Concentration: Adult males: Fe- 57, 90 µg/m ³ , Soot- 250 µg/m ³ , Fe+Soot- Fe: 45 µg/m ³ , Total PM: 250 µg/m ³ ; Neonates: Fe+Soot- Low: Fe- 30 µg/m ³ , Total PM: 250 µg/m ³ , High: Fe- 100 µg/m ³ , Total PM: 250 µg/m ³ Time to Analysis: Adult males exposed to Fe, soot, Fe+Soot, or filtered air. Exposed 6h/d, 3d (consecutive). BAL performed within 2h postexposure, lung tissue evaluations 24h postexposure. Pregnant dams housed from GD 3 to weaning at 21d-old. Neonatal rats exposed to Fe+Soot 10-12d-old and 23-25d-old. | Fe: Only the high dose had significant effects. This dose increased total protein in the lavage fluid, decreased total antioxidant power, induced GST activity, and induced a non-significant, increasing trend of GSH and GSSG. IL-1β, intracellular ferritin, and NF-κB increased. Fe+Soot, Soot: Fe+Soot significantly reduced the total antioxidant power in BALF and supernatant from lung tissue homogenate. Fe+Soot significantly increased GSSG, IL-1β, NF-κB, CYP1A1, and CYP2E1. CYP2B1 increased but was not significant. Soot alone was not significant for anything. Neonates: The high-dose significantly decreased cell viability, increased LDH activity, and increased IL-1β and ferritin. Both doses significantly increased GSSG, GRR, and GST, and decreased total antioxidant power. |
| Reference: Pires-Neto et al. (2006, 096734) Species: Mouse Gender: Male Strain: Swiss Age: 6d | Ambient Air: PM _{2.5} , NO ₂ and CB (Sao Paulo, Brazil) Particle Size: PM _{2.5} | Route: Whole-body Inhalation Dose/Concentration: PM _{2.5} : 46.49 µg/m ³ Control: 18.62 µg/m ³ NO ₂ : 59.52 µg/m ³ Control: 37.08 µg/m ³ CB: 12.52 µg/m ³ Control: 0 µg/m ³ Time to Analysis: 24h/d, 7d/wk for 5mo (weaned at 21d into exposure - mothers removed) | Nasal Cavity: Increased total mucus and acidic mucus at proximal and medial areas of cavity. Nonsecretory epithelium declined. No significant changes in amount of neutral mucus, volume proportion of neutral mucus, volume proportion of total mucus, thickness of epithelium, volume proportion of nonsecretory epithelium or ratio between neutral and acidic mucus were observed. Types of Acidic Mucus Cells: Proximal and medium cells increased. Effects on distal cells were equivocal. |
| Reference: Pourazar et al. (2005, 088305) Species: Human Gender: Male and Female (nonatopic & nonsmokers) Age: 21-28yrs | DEP: generated from idling Volvo diesel engine DEP 300 µg/m ³ comprised of: NO ₂ 1.6ppm CO 7.5ppm Hydrocarbons 4.3ppm Formaldehyde 0.26mg/m ³ Suspended particulates 4.3x10 ⁶ /cm ³ Particle Size: < 10µm | Route: Whole-body exposure chamber Dose/Concentration: DEP 300 µg/m ³ Time to Analysis: Single exposure for 1h. Parameters measured 6h post exposure. | Transcription Factors: Exposure induced increased cytoplasmic and nuclear immunoreactivity of phosphorylated p38 MAPK in bronchial epithelium. Increased nuclear translocation of phosphorylated p38 and JNK MAPK as well as increased nuclear phosphorylated tyrosine immunoreactivity were observed. No change in total or nuclear c-fos immunoreactivity was seen. Exposure induced increased nuclear translocation of phosphorylated JNK significantly associated with phosphorylation of nuclear c-jun and also resulted in an increase in nuclear p65. Cytokines: Expression of IL-8 was positively associated with nuclear phosphorylated p38 post-exposure. |

| Reference: Pradhan et al. (2005, 096128) Species: Rat Gender: Female Strain: Wistar Albino Weight: 120-180g | RSPM: Respirable Suspended PM (Lucknow, India) Quartz dust (positive control) Particle Size: < 5 μ m | Route: IT Instillation Dose/Concentration: 2.5, 5.0, or 10.0mg/0.05ml; 20, 42, 83 mg/kg Time to Analysis: Sacrificed 15d post single exposure. | Relative Lung Weight: A dose-dependent increase in total lung weight of RSPM-instilled animals was observed. BALF Cells: Exposure induced a dose-dependent increase in total cells dose-dependent with the low and mid dose levels. PMNs increased massively at all dose levels with RSPM inducing less of an increase than Quartz. Exposure at low dose levels resulted in an influx of inflammatory cells (predominantly macrophages into lumen of alveolar ducts and alveoli). Reaction at the high dose was more intense than that seen in mid dose-exposed lungs. BALF Inflammatory/Injury Markers: A significant dose-dependent increase in LDH and NO was observed, but the Quartz-induced increase was greater than the RSPM-induced increase. An increase in protein was significant at the mid dose level for RSPM and significant at the high dose level for both RSPM and Quartz. Lung biochemistry: An increase in lipid peroxidation was dose-dependent. Superoxide dismutase (SOD) enzyme levels showed a dose-dependent decrease. |
| Reference: Ramos et al. (2009, 190116) Species: Guinea Pig Gender: NR Strain: -- Age: NR Weight: 330-370g | WS (Pine wood) (CO(< 80ppm), CO ₂ (0.35%), O ₂ (20.1%), PM _{2.5} , PM ₁₀) Particle Size: PM _{2.5} , PM ₁₀ | Route: Whole-body Inhalation Chamber Dose/Concentration: WS: 60g, PM _{2.5} : 363 \pm 23 μ g/m ³ , PM ₁₀ : 502 \pm 34 μ g/m ³ Time to Analysis: Exposed 3h, 5d/wk for 1, 2, 3, 4, 6, 7m. | WS significantly decreased body weight between 4 and 7m exposure. The concentration of blood carboxyhemoglobin increased. Recovered BAL cells were higher in WS-exposed pigs. Macrophages and neutrophils increased. Inflammation in the lungs was seen. Pulmonary arterial hypertension and emphysematous lesions were observed. Macrophage and lung tissue homogenate elastolysis increased. Collagenolysis increased. Generally, MMP-2, MMP-9, and MMP-1 increased. BAL macrophage apoptosis increased with time. |
| Reference: Rao et al. (2005, 095756) Species: Rat Strain: Sprague-Dawley Weight: 175g | DEP: SRM 2975 Particle Size: 0.5 μ m | Route: IT Instillation Dose/Concentration: 5, 35, 50mg/kg bw Time to Analysis: Sacrificed 1, 7, 30d post single exposure. Cytokines measured after 24h incubation (in vitro). | BALF Inflammatory/Injury Markers: Increased albumin at 1 and 30d at all dose levels. Increased LDH except at low dose at 7d. BALF Cells: Macrophages unaffected. Increased PMNs at 1d for all dose levels, sustained elevation at 7d for mid and high dose and at 30d for all dose levels. Cytokines: The high dose induced a significant increase of mRNA expression for IL-1 β , iNOS, MCP-1, and MIP-2 in BAL cells. MCP-1 mRNA sustained high levels at 7d for mid and high dose and at 30d for all dose levels. mRNA expression of IL-6, IL-10, TGF- β 1, TNF- α were unaffected. However, IL-6 and MCP-1 proteins increased significantly in BALF at 1d for mid and high dose, returning to basal levels at 7d. MIP-2 increased for all dose levels at all time points. NO level unaffected. |

| Reference: Reed et al. (2006, 156043) Species: Rat, Mouse Gender: Male and Female Strain: CDF (F344)/CrIBR (rat), SH (rat), A/J (mouse), and C57BL/6 (mouse) Age: 6-12wks | HWS (burned mix of hardwood in noncertified wood stove using a Pineridge model 27000, Heating and Energy Systems, Inc. Clackamas, OR) Measured Components: EC, OM, NO ₃ , SO ₄ , NH ₄ , metals Particle Size: ~ 0.25µm | Route: Whole-body Inhalation Dose/Concentration: Low: 30 µg/m ³ Mid-low: 100 µg/m ³ Mid-high: 300 µg/m ³ High: 1000 µg/m ³ Time to Analysis: 6hr/d, 7d/wk for 1wk or 6m. Immediate post-exposure analysis. | Organ weights: Liver declined in rats of both genders at 1 wk and female rats at 6m. Lung volume increased and lung weight decreased in female rats at 6m. Spleen weight increased in female mice and rats at 1wk. Thymus weight decreased in male rats at 1wk. Clinical Chemistry: Cholesterol decreased at the high dose for male rats at 1wk and 6m and increased at mid-low and mid-high doses for female rats at 6m. ALP decreased for rats of both genders at 1wk and 6m for mid-low, mid-high and high dose levels (14-38%). AST decreased by 24% in male rats at 1wk with high dose. No effect on females. Creatinine serum levels decreased in males at 1wk at mid-high and high dose by 13%. No effect observed at 6m. BUN/Cre ratio decreased in females at 1wk (25%) and both genders at 6m at mid-high and high dose (18-19%). Hematology: Hemoglobin and hematocrit increased in 6mo male rats. Bilirubin increased in female rats at 6m at high dose. Platelets increased for male and female rats at 1wk (21%, 19% respectively). No effect observed at 6m. WBC increased in males at 1wk. Cells: Eosinophils decreased and lymphocytes increased in males at 6m. Neutrophils decreased at 6m in both genders. Minimal increases in alveolar macrophages and sparse brown-appearing macrophages in all species. Bacterial Clearance: Mice instilled with bacteria were mostly unaffected by exposure, except for a decline in histopathology summary score after 6m. Tumorigenesis: No values for exposed groups differed significantly from controls. There was no evidence of progressive exposure related trend. |
| Reference: Reed et al. (2004, 055625) Species: Rat, Mouse Gender: Male and Female Strain: CDF (F344)/CrIBR (rat), A/J (mouse) Age: 12wks | DE: generated from two 2000 model 5.9 L Cummins ISM turbo diesel engines Co-exposure to 8 gas and 8 solid exhaust components measured Particle Size: 0.10 - 0.15µm | Route: Whole-body Inhalation Dose/Concentration: Low: 30 µg/m ³ Mid-low: 100 µg/m ³ Mid-high: 300 µg/m ³ High: 1000 µg/m ³ Time to Analysis: 6h/d, 7d/wk for 1wk or 6m. Analyzed 1d post-exposure. | Organ weights: Kidney weight increased after 6m for both males and female rats at the high dose. Kidney and liver weight increased for female mice at all dose levels at 6m. Lung weight increased at high dose at 6m for female mice and male rats. Spleen weight decreased in male mice at the low and mid-high levels. Clinical Chemistry: There was a massive decrease in cholesterol (24%) for rats of both genders after 1wk and a smaller decrease for male rats at 6m. GGT significantly increased at 6m for male and female rats at the mid-high and high dose. ALP increased in male rats at 1 wk by 10%. AST decreased at mid-high (15%) and high dose in female rats at 6m. BUN and BUN/Creatine declined (19%, 17%) in female rats at mid-high and high doses after 6m. BUN increased by 21% at mid-low, mid-high and high doses in male rats at 1wk. Hematology: WBC decreased in high females after 6m. Factor VII (blood clotting) decreased in MH and HR males after 1wk and male and female HR after 6m. Thrombin-antithrombin complex declined massively but only in males after 1wk. Cells: Minimal increases in alveolar macrophages and PM within the macrophages were seen. Cytokines: TNF-α decreased in female rats after 6m. Tumorigenesis: No significant effect was observed. |

| Reference: Reed et al. (2008, 156903) Species: Mouse Gender: Male, Female Strain: C57BL/6, A/J, BALB/c Age: NR Weight: NR | GEE (2 1996 General Motors 4.3-L V-6 engines; unleaded gasoline) Particle Size: 150nm (MMAD) | Route: Whole-body Inhalation Dose/Concentration: Control: 2.5 ± 2.9 , Low-exposure: 6.6 ± 3.7 , Mid-exposure: 30.3 ± 11.8 , High-exposure: 59.1 ± 28.3 $\mu\text{g}/\text{m}^3$ Time to Analysis: Exposed 6h/d, 7d/wk, 3d-6m. | Body and organ weight and histopathology in A/J: Kidney weight decreased, but no effects pertaining to weight were significant. No visible inflammatory changes were seen. Lung Damage in A/J: No significant effect was seen, but hypomethylation was seen in females at 1wk, and methylation was reduced in all exposed female groups. Bacteria in lungs of C57BL/6: Exposure did not affect the clearance of bacteria from the lung. Respiratory allergic response in BALB/c: Exposure had little effect, but serum total IgE increased significantly for the high-exposure group. Increasing trends were seen in OVA-specific serum IgE and IgG1, as well as neutrophils and eosinophils. |
| Reference: Reed et al. (2008, 156903) Species: Rat Gender: Male, Female Strain: CDF (F344)/CrIBR, SH Age: NR Weight: NR | GEE (2 1996 General Motors 4.3-L V-6 engines; unleaded gasoline) | Route: Whole-body Inhalation Dose/Concentration: Control: 2.5 ± 2.9 $\mu\text{g}/\text{m}^3$, Low-exposure: 6.6 ± 3.7 $\mu\text{g}/\text{m}^3$, Mid-exposure: 30.3 ± 11.8 $\mu\text{g}/\text{m}^3$, High-exposure: 59.1 ± 28.3 $\mu\text{g}/\text{m}^3$, High filtered exposure: 2.3 ± 2.6 $\mu\text{g}/\text{m}^3$ Particle Size: 150nm (MMAD) Time to Analysis: Exposed 6h/d, 7d/wk, 3d-6m. | Body and organ weight and histopathology in F344: There were no significant effects pertaining to weight, but heart weight increased and seminal vesicle weight decreased. No visible inflammatory changes were seen. Serum chemistry, hematology, clotting factors in F344: Serum alanine aminotransferase, aspartate aminotransferase and phosphorous decreased in females at 6m in the mid- and high-exposure groups. Hematocrit, red blood cell count and hemoglobin increased at 1wk and 6m in males and females in the mid- and high-exposure groups. Plasma fibrinogen increased in males at 1wk in the mid-exposure group. Lung DNA Damage in F344: No significant effect was seen, but hypermethylation occurred in male rats at 6m in the mid- and high-exposure groups. BALF in F344: Generally, in the high-exposure group, increases were seen in LDH and MIP-2, and decreases were seen in hydrogen peroxide produced by unstimulated macrophages and superoxide by both stimulated and unstimulated macrophages. SH: HR or ECG parameters were not affected. In the high-exposure group, lipid peroxides increased in males and TAT decreased in males and females. |
| Reference: Reed et al. (2008, 156903) Species: Mouse Gender: Male, Female (only BALB/c) Strain: C57BL/6, A/J, BALB/c Age: NR Weight: NR | GEE (two 1996 General Motors 4.3-L V-6 engines; regular, unleaded, non-oxygenated, non-reformulated gasoline blended to US average consumption for summer 2001 and winter 2001-2002- Chevron-Phillips) Particle Size: MMAD: 150nm | Route: Inhalation Exposure Chamber Dose/Concentration: PM: Low- 6.6 ± 3.7 $\mu\text{g}/\text{m}^3$, Medium- 30.3 ± 11.8 $\mu\text{g}/\text{m}^3$, High- 59.1 ± 28.3 $\mu\text{g}/\text{m}^3$ Time to Analysis: A/J- 2wk quarantine period in chamber. Exposed 6h/d, 7d/wk, 3d-6m. C57BL/6- 1wk exposure. Instillation of <i>P. aeruginosa</i> . Killed 18h postinstillation. BALB/c- Conditioned to exposure chambers and mated. Pregnant females exposed GD 1 and throughout gestation. Offspring exposures continued until 4wks-old. Half of offspring sensitized to OVA. Tested for airway reactivity by methacholine challenge 48h postinstillation and euthanized. | The kidney weight of female A/J mice decreased at 6m and was strongly related to PM by the removal of emission PM. PM-containing macrophages increased by 6m. Hypomethylation occurred in females at 1wk. The clearance of <i>P. aeruginosa</i> was unaffected by exposure. Serum total IgE significantly and dose-dependently increased. OVA-specific IgE and IgG1 gave slight exposure-related evidence but were not significant. |

| Reference: Reed et al. (2008, 156903) Species: Rat Gender: Male, Female Strain: CDF (F344)/CriBR, SHR Age: NR Weight: NR | GEE (two 1996 General Motors 4.3-L V-6 engines; regular, unleaded, non-oxygenated, non-reformulated Chevron-Phillips gasoline, U.S. average consumption for summer 2001 and winter 2001-2002) Particle Size: MMAD: 150nm | Route: Inhalation Exposure Chamber Dose/Concentration: PM: Low- $6.6 \pm 3.7 \mu\text{g}/\text{m}^3$, Medium- $30.3 \pm 11.8 \mu\text{g}/\text{m}^3$, High- $59.1 \pm 28.3 \mu\text{g}/\text{m}^3$ Time to Analysis: 2wk quarantine period in chamber. Exposed 6h/d, 7d/wk, 3d-6m. SHR-surgery to implant telemeter in peritoneal cavity. 4wks recovery. ECG data obtained every 15min beginning 3d preexposure, 7d exposure, 4d postexposure. | Organ Weight: At 6m exposure, the heart weights of male and female rats increased and male rats' seminal vesicle weight decreased. Histopathology: PM-containing macrophages increased by 6m. Serum Chemistry: Serum alanine aminotransferase, aspartate aminotransferase, and phosphorus decreased in medium and high-exposure females. Hematology, Clotting Factors: Hematocrit, red blood cell count, and hemoglobin dose-dependently increased for both genders at both time points. Plasma fibrinogen increased at 1wk in males. Lung DNA Damage: Hypermethylation occurred in medium- and high-exposure male rats at 6m. BAL: For both genders in the high-exposure group, LDH and MIP-2 significantly increased at 6m. ROS decreased at 1wk and 6m. Generally, the production of hydrogen peroxide and superoxide decreased in the high-exposure group and medium- and high-exposure groups, respectively. CV effects in SHR: Lipid peroxides were significantly increased in males in the high exposure group. TAT complexes decreased in females in the high exposure group. Removal of Emission PM: The removal of emission PM strongly linked PM to increased seminal vesicle weight, red blood cell counts, LDH, lipid peroxides, and methylation. |

BALF Inflammatory/Injury Markers: UTO and UCB also increased total protein content only at the 500 μg dose. UCB induced LDH release at 125 and 500 μg . UTO and CB at 500 μg . UTO and UCB induced large dose-dependent increases in GGT activity (only statistically significant at 500 μg for UTO). Phagocytosis: All 4 particles decreased but only at the 500 μg level. Chemotaxis: Only UTO and UCB at 500 $\mu\text{g}/\text{l}$ increased chemotactic migration. |
| Reference: Rhoden et al. (2004, 087969) Species: Rat Gender: Male Strain: Sprague-Dawley Weight: 250-300g | CAPs (Boston, MA) Particle Size: CAPs: 0.1-2.5 μm | Route: Whole-body Inhalation Dose/Concentration: $1060 \pm 300 \mu\text{g}/\text{m}^3$ Time to Analysis: Single exposure for 5h. Analyzed 24 h post exposure. (CAPS-NAC = CAPS with 50mg/kg bw NAS (N-acetylcysteine) pretreatment) | Particle Characteristics: Major components did not appear to show any correlation to total particle mass. Included Na, Mg, Al, Si, S, Cl, K, Ca, Ti, V, Cr, Mn, Fe, Ni, Cu, Zn, Br, Ba, Pb. Metals Al, Si and Fe (somewhat less for Pb, Cu, K) correlated with TBARS. Oxidative Stress: CAPS increased TBARS and oxidized protein by 2+ fold. NAS fully prevented the increase in TBARS and partially prevented an increase in protein carbonyl. Tissue Damage: Wet/dry ratio increased with CAPS but significantly decreased with NAC. BALF Cells: CAPS increased PMN 4 fold. NAS treatment reduced this increase to control levels. BALF Inflammatory/Injury Markers: LDH and total protein not affected. Histology confirms slight inflammation with CAPS and no inflammation with CAPs-NAC. |

| Reference: Rhoden et al. (2008, 190475) Species: Rat Gender: Male Strain: SD Age: NR Weight: 300g | Urban Air Particles (UAP) (SRM 1649) Particle Size: NR | Route: IT Instillation Dose/Concentration: 1mg in 100 μ L saline Time to Analysis: Some rats pre-treated with MnTBAP 2h prior to UAP exposure. Instilled with UAP. CL analysis 15min postexposure. Anesthetized 4h postexposure for BAL measurements. | UAP significantly increased the total cell number, PMN, MPO activity, and protein levels. MnTBAP prevented UAP-induced lung inflammation. UAP increased oxidants in lung CL, which was prevented by MnTBAP. |
| Reference: Rivero et al. (2005, 088053) Species: Rat Gender: Male Strain: Wistar Age: 3m Weight: 250g | Ambient Air (Sao Paulo, Brazil) Particle Size: < 2.5 μ m | Route: IT Instillation Dose/Concentration: 100 or 500 μ g/rat; 0.4 or 2mg/kg Time to Analysis: single, 24h | Hematology: Reticulocytes increased at both doses. At the high dose, hematocrit, percent segmented, percent neutrophils increased and percent lymphocytes decreased (relative to control or 100 - very high variability). Fibrinogen decreased at low dose but not at high dose. Histopathology: At both doses, acute alveolar inflammation was observed and was more pronounced in the 500 μ g group. Lung Morphometry: Lumen wall ratio values show a dose-dependent increase in peribronchial as well as intra-acinar pulmonary arterioles. No effect in myocardial arterioles were observed. Tissue Damage: Increase in the heart wet/dry ratio at high dose was observed. Lung wet/dry ratios were unaffected. |
| Reference: Roberts, E.S. Charboneau, L. Espina, V. 2004 Species: Rat Gender: Male Strain: Sprague-Dawley Age: 60-90d Weight: 300-350g | ROFA: SRI (cyclone power plant) Particle Size: NR | Route: IT Instillation Dose/Concentration: 0.5 mg/rat; 1.67mg/kg Time to Analysis: Single, 6 and 24 h | Technology: Laser capture microdissection of airway cells were used to analyze results. Protein: pERK1/2: ERK1/2 ratio increased by 60% at 6h and 80% at 24 h. NFkB activity increased at 6h but was not statistically significant. |
| Reference: Saber et al. (2005, 097865) Species: Mouse Gender: Female Strain: TNF(-/-) (B6, 129S-Tnfr1Gk1), C57/BL Age: 9-10wks | DEP: SRM 2975 CB: Printex 90 (Degussa) Particle Size: DEP: 215nm; CB: 90nm | Route: Nose-only Inhalation Dose/Concentration: DEP: 20 mg/m ³ ; CB: 20 mg/m ³ Time to Analysis: 90min/d for 4d consecutively, 1h | BALF Cells: Neutrophils increased significantly to 15% when compared to control (4%) with DEP exposure. No response difference was observed between TNF (+/+) and TNF(-/-). CB did not induce any changes in neutrophil numbers. Cytokines: IL-6 increased 2-3 fold in DEP and CB exposure in both normal and knockout mice. IL-1 β was unaffected. mRNA: In TNF (+/+) mice, DEP and CB increased expression of TNF mRNA 2- fold. IL-6 mRNA expression was high in DEP-exposed knockout mice when compared to normal mice. DNA: DNA strand breaks increased in both strains. Knockout mice showed a higher response to CB and DEP exposure. For normal mice, only CB induced a statistically significant effect. |
| Reference: Schins et al. (2004, 054173) Species: Rat Gender: Female Strain: Wistar Weight: 350-550g | Soluble fractions PMC: PM _{10-2.5} PMF: PM _{2.5} -B: Borken, Germany (rural) -D: Duisburg, Germany (industrialized) Particle Size: PM _{10-2.5} , PM _{2.5} | Route: IT Instillation Dose/Concentration: 0.32 \pm 0.01 mg/rat; 0.91 \pm 0.58 mg/kg Time to Analysis: single, 18h | Radical Formation: Formation of hydroxyl radicals increased with exposure. Relative intensity is as follows: PMC-D, PMF-D, PMC-B, PMF-B, and control. Cytokines: TNF- α and IL-8 increased with PMC from both sites. PMF induced a slight increase in IL-8 but did not induce an increase in TNF- α . BALF cells: Both PMC showed a massive increase in neutrophils. PMC-B induced the greatest increase followed by PMC-D. Both PMF did not induce a significant increase. BALF Inflammatory/Injury Markers: PMC from both sites induced markedly higher endotoxin concentration vs PMF as follows in decreasing order: PMC-B, PMC-D, PMF-B, PMF-D, control. Glutathione decreased only for PMC-B. LDH and total protein were unaffected. |

| Reference: Seagrave et al. (2005, 088000) Species: Rat Gender: Male Strain: F344/DCrl BR Age: 11 ± 1 wk | PM from 3 sources: NT: New Technology bus, Detroit Diesel 50G, exhaust oxidation catalyst, 216 miles, 2002 model - in use NE: Normal emitter bus, Detroit Diesel 50G, no catalyst, 134259 miles, 1997 model - in use HE: High Emitter bus, Cummins L10G, no catalyst, > 250, 000 miles, 1992, retired Fuel composition very similar for 3 vehicles: methane (96-96.8%), ethane (1.6-1.9%), carbon dioxide (0.9-1.1%), nitrogen (0.6-0.8%), traces of other gases Particle Size: NR | Route: IT Instillation Dose/Concentration: 0.25 - 2.2 mg/rat in 0.5mL saline Time to Analysis: Sacrificed 24h post single instillation. | Engine Specific Emission data: HE had significantly higher PM and SVOC recovered emission rates than NE and NT. Organic mass in PM: The following PM sources are listed in decreasing order of percent of total mass: HE, NE, NT. Total PAH: The following PM sources are listed in decreasing order of total mass: HE, NT, Control, NE. Nitro PAH: The following PM sources are also listed in decreasing order of total mass: NE, HE, Control, NT. Authors note confounding technical issues (mostly technique related) with mostly mild effects. BALF Inflammatory/Injury Markers: LDH showed dose-dependent increases with HE inducing higher increases than NT and NE. Total protein exhibited dose-dependent increases with HE, NT and the positive control SRM2975 inducing higher levels than NE. Potency Factors Cytotoxicity and Inflammation: HE was significantly more potent than NT and NE, with NT also showing significant potency. Lung Toxicity: The results were highly variable but the general toxicity levels in increasing order is the following: NE, NT, HE, Normal gasoline, diesels, and high gasolines, though individual factors may differ greatly. |
| Reference: Seagrave et al. (2006, 091291) Species: Rat Gender: Male Strain: F344/Crl BR, Age: 11 ± 1 wk | PM _{2.5} sources: BHM: Birmingham, Alabama; urban JST: Jefferson Street, Atlanta, Georgia; urban PNS: Pensacola, Florida; urban/residential CTR: Centreville, Alabama; rural "smoke" = downwind of forest fires/burns (NR) Particle Size: PM _{2.5} | Route: IT Instillation Dose/Concentration: 0.75, 1.5, 3 mg/rat Time to Analysis: Sacrificed 24h post single instillation. | BALF Total cells and PMN: In general, the winter samples induced greater increases in potency than the summer samples except for PNS. For the winter samples, the samples that induced the greatest increases, in descending order, are: JST, BHM, CTR, PNS and Smoke. For the summer, the samples that induced increases, in descending order, are: BHM, JST, PNS, and CTR. BALF macrophages: For the winter, the BHM and JST samples significantly increased potency whereas the PNS sample induced significantly negative potency. For the summer, only the BHM sample significantly induced potency. BALF lymphocytes: Only the JST-W and BHM-W significantly increased potency. The BHM-S, CTR-S and PNS-S also significantly increased potency. Histopathological Inflammation: All the winter and summer samples, excepting PNS, significantly induced potency. Lung weight/body weight ratio: In general, for all end points, JST-S was significantly less potent than JST-W. The summer samples of BHM and CTR were also generally more potent than their winter counterparts. |

| Reference: Seagrave et al. (2005, 088000) Species: Rat Gender: Male, Female Strain: CDF(F-344)/CrIBR Age: 10-12wks | DE: (Two 6 cyl Cummins ISB turbo) HWS = hardwood smoke (mixed black/white oak, uncertified conventional wood stove) DE: EC = 557 OC = 269 $\mu\text{g}/\text{m}^3$ NO = 45 ppm NO ₂ = 4 ppm CO = 30 PPM THV = 2 ppm HWS: EC = 43 OC = 908 $\mu\text{g}/\text{m}^3$ NO or NO ₂ = 0 ppm CO = 13 ppm THV = 3 ppm Particle Size: DE: 0.14 \pm 1.8 μm | Route: Whole-body Inhalation Dose/Concentration: 30, 100, 300, 1000 $\mu\text{g}/\text{m}^3$ TPM HWS: 0.36 \pm 2.1 μm (MMAD + GSD) Time to Analysis: 6h/d, 7d/wk for 6m. 1d post-exposure | Particle Characteristics: Major differences K: HWS > > DE; Ca DE > > HWS; Zn: DE > > HWS. BALF Inflammatory/Injury Markers: LDH was unaffected by DE. Exposure to HWS induced an increase for males only at 100 and 300 but not at 1000 $\mu\text{g}/\text{m}^3$. Protein was unaffected by DE. HWS exposure showed male-only effects at 100 and 300 $\mu\text{g}/\text{m}^3$ but not at 1000. AP was unaffected by DE or HWS except for slight decline induced by HWS at 1000 $\mu\text{g}/\text{m}^3$ for both genders. Other: β -glucose was unaffected by DE. HWS-exposed females showed decreased β -glucose at 100 and 300 but not at 1000 $\mu\text{g}/\text{m}^3$. BALF GSH to (GSH+GSSG): No effects for DE were observed. HWS significantly decreased the ratio in both males and females at 1000 $\mu\text{g}/\text{m}^3$. The effect for females was greater than the male effect. BALF Cells: No effects were observed except for an increase in macrophages at 30 $\mu\text{g}/\text{m}^3$ for HWS males exposed to HWS. Cytokines: IL-1 β was unaffected by DE or HWS. MIP-2 decreased for both genders at 1000 HWS. TNF- α decreased in females with DE exposure. No TNF- α effects for HWS were observed. |
| Reference: Seagrave et al. (2008, 191990) Species: Rat Gender: Male Strain: SD Age: 10-12wks Weight: 250-300g | GEE (2 1996 General Motors 4.3-L V6 gasoline engines; conventional Chevron Phillips gasoline, U.S. average composition) (CO, NO, NO ₂ , SO ₂ , THC) (PM _{2.5} composition-EC, OC, SO ₄ , NH ₄ , NO ₃) Simulated downwind coal emission atmospheres (SDCAs) (fly ash, gas-phase pollutants, sulfate aerosols, NO, NO ₂ , SO ₂) Paved Road Dust (RD) (Los Angeles, CA; New York City, NY; Atlanta, GA) Particle Size: GEE: MMAD-150nm, RD: 2.6 \pm 1.7 μm , SDCA: 0.1-1.0 μm | Route: Nose-only Inhalation Dose/Concentration: GEE: 60 $\mu\text{g}/\text{m}^3$, SDCAs: 317-1072 $\mu\text{g}/\text{m}^3$, RD: 306-954 $\mu\text{g}/\text{m}^3$, GEE: CO-104ppm, NO- 16.7ppm, NO ₂ - 1.1ppm, SO ₂ - 1.0ppm, THC- 12ppm; SDCAs: CO- < 1ppm, NO- 0.19-0.62ppm, NO ₂ - 0.10-0.37ppm, SO ₂ - 0.07-0.24ppm, THC- < 1ppm Time to Analysis: Quarantined 2wks. 6h exposure then ip injected. Cannula ligated into trachea and connected to rodent ventilator. Thorax and abdomen opened. Killed after measurements taken. | GEE produced CL in the lungs, heart, and liver. RD produced a significant effect in the heart at the low dose. SDCAs had no effect on CL. RD significantly increased the heart's oxidative stress, as demonstrated by the TBARS levels. GEE did not affect the amount of macrophages or PMN. SDCAs increased macrophages. The RD low dose increased macrophages and PMN. SDCAs increased P _{enth} values and tidal volumes. |
| Reference: Singh et al. (2004, 087472) Species: Mouse Gender: Female Strain: CD-1 Age: 6-8wks | A-DEP (4cyl light duty 2.7l Isuzu diesel at 6 kg/m) DEP: SRM 2975 Particle Size: A-DEP > 50 μm | Route: Oropharyngeal Aspiration Dose/Concentration: 25 or 100 $\mu\text{g}/\text{mouse}$ Time to Analysis: single, 4h (18h post-exposure measurements taken but NR due to similar results) | Particle Characteristics: DEP had 60% EC vs 9% in A-DEP. A-DEP had 50% OC vs 5% in DEP. Phenanthrene and Fluoranthene fractions were much more prevalent in PAH from DEP than A-DEP. BALF Inflammatory/Injury Markers: Microalbumin increased for both pollutants except DEP induced increases only at 100 μg . Endotoxin increased microalbumin. NAG increased with 100 μg A-DEP. BALF Cells: PMNs significantly increased dose-dependently with DEP and remained elevated at 18h. Endotoxin induced the greatest increases of PMNs. Macrophages increased with A-DEP and were unaffected by DEP. Cytokines: Endotoxin induced massive responses for IL-6, MIP-2 and TNF- α but no response from IL-5. A-DEP increased all 4 cytokines but only at the 100 μg dose level. Similarly, DEP only increased IL-6 at the 100 μg dose level. |

| Reference: Smith et al. (2003, 042107) Species: Rat Gender: Male Strain: Sprague-Dawley Age: 11-12wks | CAPs (Fresno, CA) Particle Size: < 2.5 μm | Route: Whole-body Inhalation Dose/Concentration: 6 exp in 2 sets of 3: Fall1 = 847 $\mu\text{g}/\text{m}^3$ Fall2 = 260 $\mu\text{g}/\text{m}^3$ Fall3 = 369 $\mu\text{g}/\text{m}^3$ Winter1 = 815 $\mu\text{g}/\text{m}^3$ Winter2 = 190 $\mu\text{g}/\text{m}^3$ Winter3 = 371 $\mu\text{g}/\text{m}^3$ Time to Analysis: 4h/d for 3 consecutive days. Parameters measured immediately following last exposure. | Particle Characteristics: Nitrate showed the highest variability near 10 fold, followed by Si, S and EC. OC concentration was relatively consistent. Metals otherwise appeared proportionate to the concentrations. BALF Cells: Total cells increased at wk1. Percent of macrophages reduced in wk2 with CAPs. Number of neutrophils increased with CAPs, but only achieved statistical significance during wk1 of the fall and winter. Lymphocytes increased but were not statistically significant. BAL cell permeability: Upon CAPs exposure, the proportion of nonviable cells were increased up to 242% when compared to controls. The fall of wk2 induced the highest significant increases followed by fall wk1, fall wk3, and winter wk3. |
| Reference: Smith et al. (2006, 110864) Species: Rat Gender: Male Strain: Sprague-Dawley Age: 8wks Weight: 260-270g | CFA: Coal Fly Ash (400 MW, Wasatch Plateau, Utah) (aerodynamic separation) Particle Size: 0.4-2.5 μm | Route: Nose-only Inhalation Dose/Concentration: 1400 $\mu\text{g}/\text{m}^3$ PM _{2.5} including 600 $\mu\text{g}/\text{m}^3$ PM ₁ Time to Analysis: 4h/d for 3 consecutive days. Parameters measured 18 or 36h post-exposure. | BALF Cells: Percent and total number of neutrophils in BALF and blood increased significantly at both 18 and 36h. Percent of macrophages decreased slightly while number of macrophages increased in bronchiole-alveolar duct regions at both time periods. Cytokines: MIP-2 and transferrin increased at 18h. IL-1 β increased at 36h. Hematology: Plasma protein increased at 18h. Lymphocyte and hematocrit percentage decreased at 36h. Other: Gamma glutamyl transferase decreased at 36h. Lung antioxidant increased at 18h. |
| Reference: Song et al. (2008, 156093) Species: Mouse, Gender: Ffemale, Strain: BALB/c, Age: 5-6wks | DEP collected from a 4JB1-type, light-duty (2740 cc), four-cylinder diesel engine operated using standard diesel fuel at speeds of 1500 rpm under a load of 10 torque. Particle Size: 0.4 μm (mean diameter) | Route: Intranasal Instillation (days 1-5), Whole-body Exposure Chamber (days 6-8) Dose/Concentration: 0.6mg/mL in 50 μL of saline (days 1-5), 6mg/ m^3 for 1h/d for 3d (days 6-8). Time to Analysis: Enhanced Pause (Penh), measured on day 9. BAL and lung tissues collected on day 10. | Airway Hyper-Responsiveness: Intranasal exposure plus aerosolized DEP caused a significant increase in methacholine-induced Penh over the control. BAL Fluid Analysis: There was no significant increase in IFN- γ in the BAL fluid following DEP treatment but there was a significant increase in IL-4 levels compared to the control. (IL-4 increase could indicate that DEP modulates Th-2 cytokines in the mouse model). DEP also induced an increase in total neutrophils and lymphocytes in the BAL when compared to the control. The nitrite concentration in BAL (indicating NO generation) was significantly greater in the DEP exposed group than the control. Histological Assessment: Peribronchial and perivascular infiltrates were more common in the group exposed to DEP than the control. Ym1 and Ym2 Expression: (see explanation in comments section) Ym1 and Ym2 transcripts were upregulated in response to DEP exposure in mice. |
| Reference: Steerenberg et al. (2006, 088249) Species: Rat Strain: CrI/WKY | Ambient air samples PMC, PMF: -I: Rome, Italy -N: Oslo, Norway -PL: Lodz, Poland -NL: Amsterdam, Netherlands Measured Components: Li, Be, B, Na, Mg, Al, K, Ca, Ti, V, Cr, Mn, Fe, Co, Ni, Cu, Zn, As, Se, Sr, Mo, Cd, Sn, Sb, Ba, Ce, Nd, Sm, Au, Hg, Tl, Pb, Bi, U, Si, Endotoxins, Cl, NO _x , SO ₄ Particle Size: PMC: 2.35-8.5 μm ; PMF: 0.12-2.35 μm | Route: IT Instillation Dose/Concentration: 1 and 2.5mg/animal Time to Analysis: Parameters measured 24h post single exposure | Particle Characteristics: Concentrations of metals were highest in Rome. Amsterdam was noted for high Mg and V. Lodz was noted for high Pb, Zn, PAH. More of PMC was composed of Fe, Mn, Al, Cr, Cu. More of PMF, on the other hand, was composed of Zn, Pb, Ni, V. BALF Inflammatory/Injury Markers: CC16 decreased substantially. Crustal material (endotoxin, Na, Cl and metals but not Ti, As, Cd, Zn, V, Ni, Se) was positively associated with short term CC16. Albumin increased. Cytokines: MIP-2 increased dose-dependently. TNF- α also increased. BALF Cells: PMNs increased. |

| Reference: Stinn et al. (2005, 088307) Species: Rat Gender: Male and Female Strain: Crl: (WIU) BR Age: 40d | DE (generated from 1.6 L VW diesel under USFTP 72) CO: 10, 37 ppm CO ₂ : 2170, 6540 ppm NO: 7.0, 22.8 ppm NO _x : 8.6, 28.3 ppm SO ₂ : 0.83, 3.09 ppm NH ₄ : ND Measured Major Components: NO, SO ₂ , 1-nitropyrene, Zi. 50% by DE weight is elemental carbon. Particle Size: 3mg/m ³ : 0.19 µm (MMAD) | Route: Nose-only Inhalation Dose/Concentration: 3 and 10 mg/m ³ 10 mg/m ³ : 0.21 µm (MMAD) Time to Analysis: 6h/d, 7d/wk for 24m; 6 m post-exposure | <p>Body Weight: Mean weight increased substantially during the first few weeks in all groups. Food consumption decreased in 1-24mo but was recovered in 24-30mo. Body weight decreased at 23mo in all categories, but recovered except in high dose males at 30mo.</p> <p>Organ Weight: Absolute weight of lungs, larynx and trachea increased from 0 to 12 to 24mo and stayed elevated at 30 mo: Low < Hi, male ~ female.</p> <p>Pulmonary Parameters: Respiratory frequency, tidal volume, and minute volume were unaffected in any group measured between 3 and 24mo. Elemental carbon increased dose-dependently in exposure groups. No male/female difference was observed, but increases were greater at 24 mo than at 18 mo.</p> <p>BALF Cells: PMNs and lymphocytes showed dose and time-dependent effects at 18 and 24 mo (no data at 30 mo). Lymphocytes increased 50 fold in high dose males at 24mo. Peripheral monocytes and neutrophils increased 3 fold in DE groups at the end of the study. Particle-filled macrophages in alveolar lumen and interstitium increased at 12, 24, 30mo in both genders at all dose levels.</p> <p>BALF Inflammatory/Injury Markers: LDH increased in dose and time-dependent manner.</p> <p>Hematology: Erythrocytes were unaffected (12, 24, 30) except in high dose females at 24 and 30 mo. Hemoglobin and hematocrit increased dose-dependently with no gender differences. Leukocytes increased in a dose- and time-dependent manner.</p> <p>Nasal Cavity Histopathology: All effects were resolved at 30 mo. Nasal cavity hyperplasia increased at the high dose at 12 and 24mo in both genders. Squamous metaplasia of respiratory epithelium increased in high dose females (12, 24mo).</p> <p>Larynx Histopathology: No effects were observed.</p> <p>Lung Histopathology: Alveolar region hyperplasia of alveolar epithelium increased at 12, 24, 30mo in both genders at all dose levels except for 12mo low dose males and females. Above lung histopathology was not time-dependent, though perhaps some small dose-dependence was observed. The following histopathology findings showed strong dose- and time-dependent increases that occurred in both genders (24-30 mo): goblet cell hyperplasia of bronchial epithelia, cuboidal/columnar hyperplasia of alveolar epithelium, chronic active inflammation and septal fibrosis.</p> <p>Tumorigenicity: Lung tumors were more prevalent in females than males and appeared to be dose-dependent. The major 3 types of tumors are the following:: bronchio-alveolar adenoma, bronchiolo-alveolar adenoma and benign keratinizing cystic cell tumors. Enhanced effects in females versus males may be the result of enhanced metabolism (body volume versus body weight) and increased respiratory volume/bw for females.</p> |

| Reference: Sureshkumar et al. (2005, 088306) Species: Mouse Gender: Male Strain: Swiss Age: 10-12wks Weight: 20-25g | GE: Gasoline Exhaust (Honda generator EBK 1200, four stroke one cyl) Including: SO ₂ = 0.11 mg/m ³ NO _x = 0.49 mg/m ³ CO = 18.7 ppm Particle Size: GE > 4 µm = 34.1 % 3-4 µm = 15.8 % 2-3 µm = 15.8 % 1.5-2 µm = 10.6 % 0.5-1.5 µm = 5.3 % < 0.5 µm = 18.4 % | Route: Nose-only Inhalation Dose/Concentration: 0.635 mg/m ³ Time to Analysis: 15min/d 7, 14 or 21d. Parameters measured less than 1h post-exposure | Cytokines: GE caused time-dependent increases in TNF-α and IL-6. IL-10 and IL-1β were unaffected. BALF Inflammatory/Injury Markers: γ-GGT, ALP and LDH increased after 2wks of GE exposure and stayed stable at 21d. Total protein slightly increased on 14 and 21d, though these increases were not statistically significant. BALF Cells: Neutrophils (%) increased at 7, 14 and 21d (stable). Total cell count, macrophages and eosinophils were unaffected. Leukocytes and lymphocytes increased, though not significantly. Histopathology: Minor changes at 7d, mild edema in alveolar region at 14d and sloughing of epithelial cells in bronchiolar region and focal accumulation of inflammatory cells in alveolar region at 21d were observed in a time-dependent manner. |
| Reference: Tesfaigzi et al. (2002, 025575) Species: Rat Gender: NR Strain: Brown-Norway Age: 7-8wks Weight: 310-330g | WS (wood stove- Vogelzang Boxwood Stove, Model BX-42E, wood- <i>Pinus edulis</i>) (CO, NO, NO _x , total hydrocarbon) Particle Size: Smaller size fraction: 0.405-0.496 µm, larger size fraction: 6.7-11.7 µm | Route: Whole-body Exposure Dose/Concentration: Target concentration (low, high exposure): 1, 10mg/m ³ ; CO- 15-106.4ppm, NO- 2.2-18.9ppm, NO _x - 2.4-19.7ppm, total hydrocarbon- 3.5-13.8ppm Time to Analysis: Exposed 3h/d, 5d/wk, 4 or 12wks. | Respiratory: Total pulmonary resistance increased for exposure groups and was significant for the low-exposure group. In exposed groups, forced expiratory flows and quasistatic compliance were lower and dynamic lung compliance higher, the latter being significant for the high-exposure group. For the high-exposure group, vital capacity slightly decreased, residual volume slightly increased, and CO-diffusing capacity had a slight, significant decrease. Histopathology: WS caused minimal to mild chronic inflammation in the epiglottis of the larynx. PAS-positive cells increased in the 30d high-exposure group. AMs increased with time and concentration. Particle-laden macrophages were seen after 90d. AB- and PAS-positive epithelial cells increased for the 90d low-exposure group. BALF: Macrophages decreased significantly in the high-exposure group. Particle-laden macrophages increased with concentration. Lymphocytes and neutrophils slightly increased in the high-exposure group. Cytokines: LDH increased slightly and protein levels decreased slightly in the high-exposure group. Cytokines were below detectable levels. |
| Reference: Tin-Tin-Win-Shwe et al. (2006, 088415) Species: Mouse Gender: Male Strain: BALB/c Age: 7wks | CB14: Printex 90 (Degussa) CB90: Flammruss 101 (Degussa) Particle Size: CB14: 14nm CB95: 95 nm | Route: IT Instillation Dose/Concentration: 25, 125, 625 µg/mouse; approx. 1, 5, 25mg/kg Time to Analysis: 1/wk for 4wks. mRNA expression in lungs and mediastinal lymph nodes measured 4h post exposure | Body weight, thymus, spleens, splenic cell count: No effects were observed. BALF Cells: Increased total cell numbers were observed for 125, 625µg CB14 (dose-dependent) and 625µg CB95. Total cell count was twice as high for CB14 at 125 and 625 µg compared to CB95. AM numbers exhibited a dose-dependent response for both CB14 and CB95 for all doses except 125µg. Lymphocyte numbers increased at 125 and 625µg for CB14 and 625µg for CB95. PMN numbers increased at 125 and 625µg for CB14 and CB95, but the response was greater with CB14. PMN numbers were proportional to dose surface area for both PM sizes. BALF Cytokines: CB14 and CB95 induced dose-dependent increases in IL-1β. TNF-α increased at 125 and 625µg dose in CB14 with the 125 dose inducing a slightly greater increase. CB14 and CB95 induced CCL-3 increases 125 and 625µg. Chemokine mRNA in lung and lymph nodes: CCL-3 mRNA increased for CB14 but not CB95 4h following the last exposure. CCL-2 was unchanged. Mediastinal lymph nodes: The number of CB-laden phagocytes increased in a dose-dependent manner for CB14 and CB95. CB14 had higher numbers at all doses compared to CB95. |

| Reference: Tong et al. (2006, 097699) Species: Mouse Gender: Male Strain: KP600 CD-1 Weight: 22-26g | PM _{2.5} (collected from stacked filter air sampler in Shanghai, China) Fe: FeSO ₄ Zn: ZnSO ₄ PMF: PM _{2.5} + FeSO ₄ PMFZ: PM _{2.5} + FeSO ₄ + ZnSO ₄ Major Measured Components: Fe 26ppm, Zn 9ppm, S 61ppm Particle Size: PM _{2.5} | Route: IT Instillation Dose/Concentration: PM: 25mg/mL, 1mg/mouse Fe: 15mg/mL, 0.6 mg/mouse Zn: 15mg/mL, 0.6 mg/mouse PMF: PM 25mg/mL + Fe 15mg/mL, 1.6mg/mouse PMFZ: PM 25 mg/mL + Fe 15mg/mL, 1.6mg/mouse Time to Analysis: Instilled twice at 0 and 24h. Parameters measured 24h following last exposure (at 48h). | Synchrotron X-ray imaging (in vivo): PMFZ showed the greatest increase in alveolar changes. Fe induced more hemorrhagic changes, whereas Zn induced more nonuniformity of lung texture. This suggests that Zn induces PBMC in a dose-dependent manner which releases IL-1, IL-6, TNF- α , and IFN- γ . Histopathology: PMFZ induced the most severe changes including serious inflammation/pus in bronchia and bronchial epidermal cell hyperplasia. For Fe or PMF hemorrhagic changes predominated but were less severe than PMFZ. |
| Reference: Upadhyay et al. (2008, 159345) Species: Rat Gender: Male Strain: SHR Age: 6m Weight: NR | Ultrafine Carbon Particles (UFCP) Particle Size: Size- 31 ± 0.3 nm, MMAD- 46nm, Surface area concentration- $0.139 \text{ m}^2(\text{particle})/\text{m}^3(\text{air})$, Mass specific surface area- $807 \text{ m}^2/\text{g}$ | Route: Whole-body Exposure Dose/Concentration: $172 \mu\text{g}/\text{m}^3$ Time to Analysis: Acclimatized 2d. 1d baseline. 24h exposure. 4d recovery. Sacrificed 1 st or 3 rd day of recovery. | Cardiophysiology: The mean arterial BP and HR increased but returned to baseline levels by the 4 th recovery day. SDNN and HRV decreased. RMSSD and LF/HF decreased but were not significant. Pulmonary Inflammation: UFCP did not cause pulmonary inflammation. Pulmonary and Cardiac Tissue: HO-1, ET-1, ETA, ETB, TF, PAI-1 significantly increased in the lung on the 3 rd recovery day. HO-1 was repressed in the heart, but the other markers had slight, nonsignificant increases. Systemic Responses: Neutrophil and lymphocyte cell differentials significantly increased on the 1 st recovery day. Other blood parameters were unaffected. The plasma renin concentration increased on the first 2 recovery days. Ang I and II concentrations increased on the 1 st recovery day but was not significant. |
| Reference: Wallenborn et al. (2007, 156144) Species: Rat Gender: Male Strain: WKY, SHRWKY, and stroke-prone SH (SHRSP) Age: 12-15wks | PM: precipitator unit power plant residual oil combustion Particle Size: PM: $3.76 \mu\text{m}$ (bulk) ± 2.15 | Route: IT Instillation Dose/Concentration: WKY vs SHRSP: 1.11, 3.33, 8.33 mg/kg SH vs SHRSP: 3.33, 8.33 mg/kg Time to Analysis: WKY vs SHRSP: single exposure, parameters measured 24h post-exposure. SH vs SHRSP: single exposure, parameters measured 24h post-exposure. Note: 4h post-exposure study done on WKY vs SHRSP but not published. | BALF Cells: A dose-dependent increase in total cells and neutrophils was observed. Equal response for all 3 strains except for SH, for both concentrations was observed. BALF inflammation/Injury Markers: LDH exhibited a dose-dependent increase in equal response for all 3 strains. WKY had higher baseline levels of NAG activity but, upon PM exposure, SHRSP induced higher increases than WKY. GGT exhibited a dose-dependent response for all 3 strains. SHRSP showed the highest increase followed by WKY and SH. Protein levels increased at the high dose level with SHRSP exhibiting the highest increases followed by SH and WKY. Albumin levels were inconsistent between experiments. Oxidative Stress - Lung: (WKY vs SHRSP only): SOD decreased following increased exposure levels with SHRSP levels generally higher than WKY. Ferritin levels declined only in SHRSP. Oxidative Stress - Cardiac: SOD increased in the SHRSP vs WKY experiment only. Only SHRSP at 8.33 mg/kg showed a significant increase when compared to the control. GPx: No action but SHRSP levels were similar to SHR and, in the WKY vs SHRSP experiment, SHRSP exhibited higher activity level than WKY. Ferritin: Equivocal results were observed. Levels decreased at the high dose for WKY and SHRSP but increased at medium doses for SH and SHRSP. ICDH: Levels increased for WKY and decreased for SHRSP. |

| Reference: Wallenborn et al. (2008, 191171) Species: Rat Gender: Male Strain: Wistar Kyoto (WKY) Age: 13wks Weight: NR | Zinc Sulfate (ZnSO ₄ , aerosolized) Particle Size: NR | Route: Nose-only Inhalation Dose/Concentration: 9.0±2.1 µg zinc/m ³ , 35±8.1 µg zinc/m ³ , 123.2±29.6 µg zinc/m ³ Time to Analysis: Exposed 5h/d, 3d/wk, 16wks. Half of the rats used for plasma/serum analysis, other half for isolation of cardiac mitochondria. | A trend toward increased BALF protein was seen. Cardiac mitochondrial ferritin had a small, significant increase. Mitochondrial succinate dehydrogenase and glutathione peroxidase had small, significant decreases. Subchronic exposure to 100 µg/m ³ caused expression changes of cardiac genes involved with cell signaling events, ion channels regulation, and coagulation. No pulmonary-related effects were seen. |
| Reference: Wegesser and Last (2008, 190508) Species: Mouse Gender: Male Strain: BALB/c Age: 8-10wks | Ambient PM _{2.5} -PM ₁₀ Collected from San Joaquin Valley, CA Particle Size: PM _{10-2.5} | Route: IT Instillation Dose/Concentration: 25-50 µg/mouse Time to Analysis: 3, 6, 18, 24, 48, 72h post IT instillation. | BALF Cells: Increased amount of viable cells found in PM-exposed mice with dose-response relationship between dose of PM and number of total cells recovered in BALF. At 6h, increased numbers of macrophages at both 25 and 50 µg/mouse. Increased percentage of neutrophils observed with 50 µg/mouse PM only. Furthermore, both macrophages and neutrophils increased with longer time period from instillation, peaking at 24 h. MIP-2: At 50 µg/mouse, MIP-2 concentrations increased, peaking at 3h, though not statistically significant and returned to basal levels by 6h. Positive correlation observed between MIP-2 concentration and increased neutrophil counts. No correlation found between MIP-2 and macrophages. |
| Reference: Whitekus et al. (2002, 157142) Species: Mouse Gender: Female Strain: BALB/c Age: 6-8wks Weight: NR | DEP (light-duty, four-cylinder engine- 4JB1 type, Isuzu Automobile, Japan; standard diesel fuel) (extracts) Particle Size: 0.5-4 µm | Route: Inhalation Dose/Concentration: 200, 600, 2000 µg/m ³ Time to Analysis: Exposed 1h/d 10d. Animals receiving OVA had 20min OVA exposure after DEP exposure. | DEP + OVA dose-dependently increased IgE and IgG1, being more effective than the OVA-alone treatment. This effect was significantly suppressed by thiol antioxidants NAC or BUC. DEP + OVA increased carbonyl protein and lipid peroxide over OVA. NAC or BUC suppressed lipid peroxide and protein oxidation. No general markers for inflammation were observed. |
| Reference: Wichers et al. (2004, 055636) Species: Rat Gender: Male Strain: SH Age: 75d | PM (HP-12): inside wall of stack of Boston, MA power plant burning # 6 oil. Particle Size: PM: 3.76 µm ± 2.15 | Route: IT Instillation Dose/Concentration: 0.83, 3.33 or 8.33 mg/kg Time to Analysis: single, 6h for Whole-body plethysmographs (WBP) and repeated daily for 4-7d, 96 or 192h post-exposure non-WBP animals: single, 24, 96, 192h post-exposure | Tidal Volume: A dose-dependent decrease in tidal volume (45 % at high dose) was sustained for 1d with very slow recovery over 7d. Breathing frequency: Dose-dependent increase (100 % at high dose) with recovery at 7d was observed. Minute ventilation: Small dose-dependent increases were observed with a return to normal ventilation in 2d. Penh (enhanced pause): Equivocal results in all groups were observed (due to major control variation). BALF Cells: Dose-dependent increases in total cells at 24 h, with declined, but still elevated, levels at 192h. Neutrophils increased significantly (10 fold) at 24 h in the mid and high dose groups and showed declined, but still elevated, levels at 192h. Macrophages slowly increased in a dose-dependent manner at 192h. BALF Inflammatory/Injury Markers: Protein and albumin increased at 24 h, returned to relative basal level at 192h at the mid and high dose levels. NAG exhibited dose-dependent increases at 24h and sustained these levels through 192h. |

| Reference: Wichers LB et al. (2006, 103806) Species: Rat Gender: Male Strain: SH Age: 71-73d Weight: 255-278g | PM (HP-12): inside wall of stack of Boston, MA power plant burning # 6 oil. Particle Size: $1.95 \mu\text{m} \pm 3.49$ | Route: Whole-body Inhalation Dose/Concentration: 13 mg/m^3 Time to Analysis: Phase I: 1st day, filtered air, 2nd day, 6h of PM Phase II: 1st Da, y filtered air, 4 days of 6h PM each Immediate post-exposure | Body/ Lung weight: No effects on Phase I rats were observed. HP-12 exposure increased body weight, left lung, right intercostal, and right diaphragmatic lobes in Phase II rats. However, results appeared due to normal growth pattern in juvenile rats over 4d. Lung lobe to Body Weight Ratio: No effects at 1 or 4d were observed. Deposition calculations: V and Co were used to estimate deposition rates (good correlation between two metals at $R^2 = 0.94$). Total HP-12 deposition using Co was 26 and $99 \mu\text{g}$ (for 1 day and 4 day experiments) and using V was 31 and $116 \mu\text{g}$. Modeling information estimated HP-12 deposition at 43% in conducting airways and 57% in alveolar region. Breathing parameters: No changes were observed for 1 or 4d studies except for a possible decrease in frequency for the 1d study. |
| Reference: Witten et al. (2005, 087485) Species: Rat Gender: Female Strain: F344 Age: 8wks Weight: ~ 175g | DEP (heavy-duty Cummins N14 research engine operated at 75% throttle) Particle Size: 7.234-294.27nm | Route: Nose-only Inhalation Dose/Concentration: Low- $35.3 \pm 4.9 \mu\text{g/m}^3$, High- $632.9 \pm 47.61 \mu\text{g/m}^3$ Time to Analysis: Exposed 4h/d, 5d/wk, 3wks. Pretreated with saline or capsaicin. | There were no differences for substance P. The low-exposure group had significantly less NK1. DEP reduced NEP activity. Plasma extraversion dose-dependently increased and was greatest in capsaicin animals. Respiratory permeability dose-dependently increased. IL-1 β was significantly higher for the low-exposure group. IL-12 was significantly lower in the capsaicin high-exposure group. TNF- α increased in the high-exposure group and capsaicin low-exposure group. High exposure induced particle-laden AMs in the lungs, perivascular cuffing consisting of mononuclear cells, alveolar edema and increased mast cell number. Neutrophil and eosinophil influx was not seen. |
| Reference: Wong et al. (2003, 097707) Species: Rat Gender: Female Strain: F344/NH Age: ~ 4wks Weight: ~ 175g | DEP (Cummins N14 research engine at 75% throttle) (EC-34.93-601.67 $\mu\text{g/m}^3$, OC-1.90-11.25 $\mu\text{g/m}^3$, Sulfates 0.94-17.96 $\mu\text{g/m}^3$, Na- 4.07-4.78 ng/m^3 , Mg- 0.60-0.86 ng/m^3 , Ca- 5.05-10.66 ng/m^3 , Fe- 3.17-6.44, Cr- 0.68-1.31 ng/m^3 , Mn- 0.11-0.22 ng/m^3 , Pb- 0.97-1.24 ng/m^3) Particle Size: 7.5-294.3nm | Route: Nose-only Inhalation Dose/Concentration: Low- $35.3 \pm 4.9 \mu\text{g/m}^3$, High- $669.3 \pm 47.6 \mu\text{g/m}^3$ Time to Analysis: Exposed 4h/d, 5d/wk, 3wks. Pretreated with saline or capsaicin. | DEP dose-dependently increased plasma extraversion, which was further increased by capsaicin. In the high-exposure group, particle-laden AMs (which were reduced by capsaicin), inflammatory cell margination, perivascular cuffing with subsequent mononuclear cell migration and dispersal, increased mast cells, and decreased substance P were all seen. NK-1R was downregulated in the low-exposure group and upregulated in the capsaicin-pretreated high-exposure group. NEP decreased significantly for both groups. |
| Reference: Wu, W. Wang, X. Zhang, W. 2003 Species: Rat Gender: Male Strain: Sprague-Dawley Age: 60d | Zn2+ Particle Size: NA | Route: IT Instillation Dose/Concentration: $50 \mu\text{m/rat}$ Time to Analysis: Single, 24 h | Cells: Decreased number of airway epithelial cells shown with PTEN protein immunostaining. Macrophages were unaffected. |

CB14 induced an increase in PMNs but the increases were not dose-dependent. LTA massively increased PMN. LTA induced dose-dependent increases in total cells, especially at high dose at 24 h. LTA had massive synergistic effect with CB14 and CB95 for total cells and PMNs. Total cell count and PMN levels were highest in 14CL with levels at 24h higher than at 4h. Macrophage data were inconsistent. Cytokines: CB95 induced dose-dependent increases in IL-6, TNF- α , CCL2 and CCL3. CB14 induced dose-dependent increase in CCL2 and CCL3. Exposure induced increases of IL-6 at the high dose only. Slight effect on TNF- α was observed. LTA induced dose-dependent increases of IL-6, TNF- α and CCL3. 14CL massively induced IL-6 and CCL2. No combination of CB and LTA affected TNF- α or CCL3. mRNA Expression: LTA, 14CL and 95CL increased TLR2 mRNA expression with 95CL and 14CL inducing higher increases than LTA. No effect on TLR4 mRNA expression was observed. |
| Reference: Yanagisawa et al. | Reference: Araujo et al. (2008, 156222) Species: Mouse Gender: Male Strain: ApoE ^{-/-} , C57BL/CJ Age: 6wks Weight: NR | CAPs (Los Angeles, California freeway; Nov-Dec 2005) Particle Size: Fine particles (FP): < 2.5 μm ; UFP: < 0.18 μm | Route: Whole-body Exposure Dose/Concentration: FP: $\sim 440 \mu\text{g}/\text{m}^3$, UFP: $\sim 110 \mu\text{m}$; PM number concentration: FP: 4.56×10^5 particles/cm ³ , UFP: 5.59×10^5 particles/cm ³ Time to Analysis: Exposed 5h/d, 3d/wk for total of 75h. Killed 24 to 48h postexposure. | Composition: UFP had a higher particle number, surface area, PAH content and fractional carbon composition than FP. Atherosclerosis: UFP had significantly greater aortic atherosclerotic lesions than FP and the control. The lesions were comprised of macrophage infiltration with intracellular lipid accumulation. Plaques were thicker and more extensive in the UFP group. HDL: FP had increased plasma total cholesterol. Plasma HDL from both groups had decreased protective effects. The anti-inflammatory effect was lower in the UFP group. Oxidative Stress: Lipid peroxidation increased in the FP group. The UFP group had increases in hepatic malondialdehyde, Nef2, catalase, glutathione S-transferase Ya, NAD(P)-quinone oxidoreductase and superoxide dismutase 2. |
| Reference: Archer et al. (2004, 088097) Species: Mouse Strain: BALB/c DO11.10+/+ transgenic - ova specific receptor for OVA peptide 323-339 Age: 4 wks | PM = SRM 1648 (NIST) Titanium dioxide (TiO ₂) as a control particle Particle Size: SRM1648: avg 1.4 μm TiO ₂ : avg 0.3 μg (sic) | Route: Intranasal instillation Dose/Concentration: 500 μg PM/30 μl sterile saline (ultrasonic suspension) initial 0-750 μg range finding Time to Analysis: Ova challenge at 68h, Methacholine aerosolization/AR at 72h | Airway responsiveness (WBP): AR induced by Ova/Mch challenge was significantly and dose-dependently increased at doses of SRM1648 $\geq 500\text{ug}$. TiO ₂ /Ova exposure was not significantly different from saline. PM associated endotoxin did not contribute to enhanced AR. Lung inflammation/pathology: No increases in BAL macrophages or eosinophils and no histological alterations after PM exposure. Both TiO ₂ and PM increased pulmonary neutrophils, indicating particles alone were responsible for this increase and that the inflammatory response could occur independently of AR. |
| Reference: Barrett et al. (2006, 155677) Species: Mouse Gender: Male Strain: BALB/c Age: 8-10wks n: Groups of 15-16 incl. controls | HWS (black/white oak) CO Total Vapor Hydrocarbon (TVH) Particle Size: 0.25 \pm 3.3, 0.35 \pm 2.5, 0.35 \pm 2.0, 0.36 \pm 2.1 μm (MMAD \pm GSD) | Route: Whole-body Inhalation Dose/Concentration: HWS: 30, 100 300, 1000 $\mu\text{g}/\text{m}^3$ CO: 0.7, 1.6, 4.0, 13ppm TVH: 0.3, 0.6, 1.3, 3.1ppm Time to Analysis: Pretreatment: ip 10 μg OVA and 2mg aluminum hydroxide post-OVA. OVA aerosol challenge on day 14, followed by 3d of HWS. Pre-OVA received aerosol OVA challenge on day 14, then 3d of HWS on days 26-28 and an immediate (second) OVA challenge HWS 6 h/d for 3d. Sacrificed 18h post-exposure. | Allergic Inflammation: A statistically significant increase in eosinophils was observed at 300 $\mu\text{g}/\text{m}^3$ HWS following OVA challenge as compared to OVA alone. No changes in macrophages, neutrophils and lymphocytes were observed. Post-OVA HWS did not significantly alter BAL cytokine or serum antibody levels, but linear trend analyses indicated decreases in IL-2, IL-4, and IFN α in the absence of OVA, as well as a statistically significant upward trend in OVA-specific IgE when HWS exposure followed OVA challenge. HWS exposure pre-OVA (prior to second OVA challenge) resulted in a decrease in IL-13 (statistically significant at the high dose but no evidence of an exposure-dependent response), an increase in OVA IgG1 (trend significant) and no change in IL-2, IL-4, IL-5, IFN α , OVA IgE, total IgE or OVA IgG2a. |

| Reference: Burchiel et al. (2004, 055557) Species: Mouse Strain: AJ Age: 10-12wks | DE generated alternatively from two 2000 Cummins ISB Turbo Diesel 5.9 L engines using no 2 (chevron) oil and 15w/40 oil (Rotella T, Shell) run according to USEPA Dynamometer Schedule for Heavy-Duty Diesel Engines 18 PAHs quantified at exposure levels (text mentions 65) Particle Size: NR | Route: Inhalation Chambers Dose/Concentration: 30, 100, 300, 1000 mg/m ³ diesel PM Time to Analysis: 6 h/d, 7 d/wk for 6m | Proliferative responses: DE depressed splenic T cell proliferation at all exposure levels but was not dose-dependent and most pronounced at the 30 µg/m ³ level. ($p < 0.05$ at all levels) Splenic B cell proliferation was increased at the 30 µg/m ³ level, but not at the other exposure levels. Little, if any, PAH was found in DE, and the majority of PAH tested in vitro enhanced T cell proliferation (below), so PAH is likely not responsible for the immunosuppressive effect of DE on murine spleen cell responses. |
| Reference: Burchiel et al. (2004, 055557) Species: Mouse Strain: AJ Age: 10-12 weeks Cell Type: spleen cells Use: In vitro | Benzo(a)pyrene (BaP) Benzo(a)pyrene-r-7,t-8-dihydrodiol-t-9,10 epoxide(±) ((antiPDE) Benzo(a)pyrene-trans-7,8-dihydrodiol (±) (BP-7,8-diol) Benzo(a)pyrene-1,6-dione (1,6-BPQ) Benzo(a)pyrene-3,6-dione (3,6-BPQ) Benzo(a)pyrene-6,12-dione (6,12 BPQ) Particle Size: NR | Route: Cell Culture Dose/Concentration: 1 x 10 ⁶ cells/mL in 100 µl aliquots 0.01, 0.1 and 1 µm Time to Analysis: 72h | BaP at the highest concentration was found to double splenic T cell proliferation. The BPQs all also increased T cell proliferation at much lower concentrations but not in a dose dependent manner. Splenic B cell was increased by Bp-(7,8)-diol, and inhibited by BPDE and 3,6 BPQ but only at the highest level. Authors concluded that due to low level of PAH in DE and absence of BPQs these compounds are not responsible for immunosuppressive effects of DE. |
| Reference: Chan (2006, 090193) Species: Mouse Strain: DO11.10, BALB/c, <i>Nrf 2</i> -/- Cell Types: Primary bone marrow dendritic cells and dendritic cell line (BC1), T cells (BMDC) | DEP: DE particles DEP methanol extract: Particle Size: PM > 50 as characterized by Singh et al. 2004 | Route: Cell Culture Dose/Concentration: DEPs 10 µg/mL LPS 5ng/mL Time to Analysis: 24h, stored at -20°C until analyzed | Dendritic cell maturation: Organic DEP chemicals interfered in the expression of several DC maturation markers. Both DEP and DEP extracts were found to inhibit CD86 expression and IL-12 production in LPS-exposed DCs, and intact particles were not as effective as DEP extract. DEP extract treatment of BC1 cells reduced their ability to stimulate co-cultured antigen-specific T cells, leading to decreased IFN- γ and increased IL-10 without affecting IL-4 or IL-13. DEP extract also induced oxidative stress and interfered with DC activation by several other Toll-like receptor agonists as well as the NF-κB cascade. Inhibition of IL-12 production by DEP extract was shown to be mediated by pro-oxidative chemicals that engage the Nrf2 pathway. Taken together the inhibition of both IL-12 and IFN- γ indicates a suppression of the Th1 pathway and provides a novel explanation for the adjuvant effect of DEPs on allergic inflammation |

| Reference: Ciencewicki et al. (2007, 096557) Species: Mouse Gender: Female Strain: BALB/c Age: 10-12wks Weight: 17-20g | DE: generated from a 30-kW (40 hp), 4-cylinder Deutz BF4M1008 diesel engine Influeza A/Bangkok/1/79 (H3N2 serotype) from Dr. Melinda Beck of the University of North Carolina, Chapel Hill O ₂ : CO, NO ₂ , NO, SO ₂ O ₂ : 20.9- 20.5% (Lo, Hi) CO: 0.9-5.4 ppm NO ₂ : 0.25-1.13 ppm NO: 2.5-10.8 ppm SO ₂ : 0.06-0.32 ppm H3N2: NR Particle Size: NR | Route: Inhalation (oropharyngeal aspiration of virus) Dose/Concentration: DE: 529 or 2070 µg/m ³ Time to Analysis: 4 h/d for 5d. Virus exposure immediately after last DE exposure. Analyzed 18h post infection | DE exposure on susceptibility to Influenza infection: Mice exposed to 0.5 mg/m ³ had significantly greater levels of HA mRNA compared to air-exposed mice. HA levels not significantly altered in mice exposed to 2.0 mg/m ³ . DE exposure on the Influenza-induced inflammatory response: IL-6 mRNA levels were significantly greater when exposed to 0.5 mg/m ³ of DE prior to infection compared to air exposure. Significantly increased amount of IL-6 protein observed in exposed mice. Exposure to DE in absence of influenza infection had no significant effect on IL-6 mRNA or protein levels. DE exposure on pulmonary injury: Infection with the influenza virus increases levels of PMN in BAL fluid. Exposure to either dose of DE prior to infection showed no significant effect on PMN levels. Exposure to DE alone had no effect on PMNs in BAL fluid. Neither exposure to DE nor infection with influenza significantly increased BAL fluid protein levels when compared to non-infected, air-exposed. Other markers of injury, NAG and MIA were not statistically affected by DE or influenza exposure. DE exposure on the influenza induced interferon response: No significant change in TFN-α mRNA levels at either dose of DE, although mice exposed to 0.5 mg/m ³ of DE prior to infection had significantly greater levels of IFN-β mRNA compared to air controls. No effect on any of the IFNs observed in uninfected mice exposed to DE. DE exposure on surfactant protein expression: Influenza virus infection alone significantly increased expression of SP-A in air-exposed. Exposure to 0.5 mg/m ³ of DE prior to infection had significant decreases in levels of SP-A mRNA in the lungs, this effect was not observed in 2.0 mg/m ³ DE exposed. Decrease seen in expression of SP-A protein in lungs of mice exposed to 0.5 mg/m ³ DE prior to infection. Levels of SP-D mRNA and protein were significantly decreased in lungs of mice exposed to 0.5 mg/m ³ of DE prior to infection compared with mice exposed to air or 2.0 mg/m ³ DE prior to infection. Exposure to 0.5 mg/m ³ of DE prior to infection with influenza decreased levels of SP-D, especially in airways. Mice exposed to 2.0 mg/m ³ DE prior to infection showed no significant difference. |
| Reference: Day et al. (2008, 190204) Species: Mouse Gender: Male Strain: BALB/c Age: 8-10wks Weight: NR | GEE (General Motors 1996 model 4.3-L V6 engine; regular unleaded fuel) (CO, NO, NO ₂ , SO ₂ , NH ₃) Particle Size: NR | Route: Whole-body Exposure Chamber Dose/Concentration: Low(L)- 6.6 ± 3.7 PM/m ³ , Medium(M)- 30.3 ± 11.8 PM/m ³ , High(H)- 59.1 ± 28.3 PM/m ³ , High-Filtered(HF)- Time to Analysis: Pre-OVA protocol: OVA or saline sensitized 7d. OVA challenge day 14. GEE or air exposed 6h/d on days 26-28. Immediately after exposure on day 28 challenged with OVA. Tested for MCh-induced changes 24h postexposure then sacrificed. Post-OVA protocol: OVA or saline sensitized 7d. OVA challenge day 14. GEE or air exposed days 15-17. Tested for MCh-induced changes 24h postexposure then sacrificed. | Post-OVA: In nonsensitized mice, neutrophils dose-dependently decreased, IL-4 decreased in the M group, IL-5 decreased in the HF group, and IFN-α decreased at all exposures. In OVA-sensitized mice, IL-13 dose-dependently decreased. Pre-OVA: In nonsensitized mice, neutrophils and IgE decreased in the H group. IL-2 increased in the HF group and was dose-dependent. Eosinophils dose-dependently decreased. OVA-specific IgE increased in the H group, and OVA-specific IgG ₂ dose-dependently increased. In OVA-sensitized mice, OVA-specific IgG ₁ increased in the M group. Airway hyperresponsiveness was lower in the M and HF groups. |

| Reference: de Haar et al. (2005, 097872) Species: Mouse Gender: Female Strain: BALB/cANNCrl Age: 6-8wks Weight: NR | CBP: Carbon black particles in phosphate buffered saline, 1: 10 & 1: 100 dilutions (Brunschwich Chemicals, Amsterdam, The Netherlands) OVA: Ovalbumin (igma-Aldrich, Zwijndrecht, The Netherlands) Particle Size: CBP: 30-50nm | Route: Intranasal Droplet Dose/Concentration: CBP ± OVA 200, 20, 2 µg (3.3, 0.33, 0.033 mg/ml) OVA only: 20 µg (0.5 mg/ml) Time to Analysis: Droplet applied on days 0, 1, 2. Sacrificed on day 4 or challenged with OVA droplet on days 25, 26, & 27. Sacrificed on day 28 | Acute airway damage and inflammation: Only day 4 had LDH increased in the 200 µg CBP + OVA group. The 200 µg CBP + OVA group induced significantly higher numbers of BAL cells compared to OVA control. Total protein and TNF-α levels were increased only in 200 µg CBP + OVA group. RAS, parameter for phagocytosis, 200 µg and 20 µg CBP + OVA had higher levels than OVA controls. Adjuvant activity on PBLN: Total lymphocytes in PBLN significantly increased 4-5 fold in the 200 µg CBP + OVA exposed. 20 µg and 2 µg exposures did not increase the number of PBLN cells compared to OVA control. All CBP + OVA concentrations induced higher levels of IL-4, IL-5, IL-10, and IL-13, with 200 µg concentration having 10-200 times higher levels. IFN-γ cytokine was increased in the 200 µg dose. IgE Production: In CBP + OVA, IgE were significantly increased. PBLN and Lung Lymphocytes after OVA challenge: PBLN cell numbers increased in OVA and CBP + OVA sensitized mice. CD4 and CD8 populations increased in both groups. PBLN levels in CBP + OVA and challenged with PBS were higher than mice treated with OVA and challenged with PBS, both groups cytokine production was low, only IL-5 levels were significant in the CBP + OVA/PBS group. Higher lung lymphocyte numbers were caused by higher numbers of CD4 and CD19. Production of IL-5 and IL-10 was four to five times higher than in OVA treated mice. OVA challenge induces asthma like airway inflammation in CBP + OVA sensitized mice: Total number of cells in BAL increased 10 fold in CBP + OVA mice challenged with OVA. Eosinophils exhibited highest increase in CBP + OVA/OVA group. Perivascular and peribronchial infiltrates and goblet cell hyperplasia in CBP + OVA/OVA was confirmed by histological examination. Antigen specific inflammation induced in CBP + OVA mice. |

| Reference: de Haar (2006, 144746) Species: Mouse Gender: Female Strain: BALB/cANNCr Age: 6-8wks Weight: NR | CBP: fine (F) and ultrafine (UF) carbon black particles (Ken Donaldson Group) TiO ₂ : fine and ultrafine titanium oxide particles (Ken Donaldson Group) OVA: Ovalbumin (Sigma-Aldrich, Zwijndrecht, the Netherlands) Particle Size: F CBP: 260.0nm UF CBP: 14.0nm F TiO ₂ : 250.0nm UF TiO ₂ : 29.0nm | Route: Intranasal Droplet Dose/Concentration: CBP: 200 µg (3.3 mg/mL) TiO ₂ : 200 µg (3.3 mg/mL) OVA: 10 µg CBP + OVA: 200 + 10 µg (see note in 3008) Time to Analysis: Days 0,1,2: Exposed to OVA or CBP + OVA. Sacrificed on day 8 & analyzed after 2h, or continued to second group. Second group: days 25, 26, 27 given OVA challenge day 28: sacrificed , analyzed 24h post sacrifice | Ultrafine particles induce lung inflammation: UF TiO ₂ and CBP induced a local inflammatory response in the airways and showed higher levels of LDH and total protein as compared to mice exposed to the F particles. Cytokine levels were much higher in groups exposed to ultrafine particles. Histologic analysis of the airways showed that exposure to ultrafine TiO ₂ or CBP leads to peribronchial and perivascular inflammatory infiltrates (mostly neutrophils). Exposure to OVA alone, or combined with fine TiO ₂ and fine CBP had no effects on lung histology. Ultrafine stimulate local immune responses: TiO ₂ and CBP particles stimulated the local immune response against co administered OVA antigen. Fine TiO ₂ particles induced a low but significant increase in PBLN cell number. Both types of ultrafine particles elicited higher levels of Th-2 associated cytokines, with UF CBP stimulating a greater response. IFN γ production was low, but significantly higher than OVA exposures. Ultrafine TiO₂ increase ovalbumin-specific IgE and IgG1 levels: Levels of OVA specific IgE were significantly increased in animals exposed to the UF TiO ₂ + OVA compared to F TiO ₂ or OVA-only. . Average IgE level in mice exposed to ultrafine CBP + OVA was not a significant increase. OVA-specific IgG2a not detected in any groups. Ultrafine particles stimulate allergic airway sensitization against ovalbumin: At day 28, the PBLN cell numbers were significantly higher in both ultrafine and combination with OVA. Production of OVA specific IL-4, IL-5, IL-10 and IL-13 by PBLN cells was significantly increased in both ultrafine TiO ₂ and CBP. IFN γ levels were significantly increased in ultrafine CBP + OVA treated animals. F TiO ₂ had low, but significant, increases in IL-4 and IFN γ compared to OVA only. Allergic airway inflammation and Influxes of eosinophils, neutrophils and lymphocytes were only found in both groups exposed to ultrafine particles. |
| Reference: de Haar (2008, 187128) Species: Mouse Gender: Female Strain: BALB/c, CD80/CD86-deficient, DO11.10 Age: 6-8wks Weight: NR | Ultrafine Carbon Black (UFCB) (Brunswick Chemicals; Amsterdam, The Netherlands) Particle Size: Diameter: 30-50nm | Route: Intranasal Exposure. IP Injection. Tail Injected. Dose/Concentration: 20 µg/mL Time to Analysis: Exposed days 1, 2, 3. Kept in supine position until recovery. OVA challenge days 25, 26, 27. Spleens and lymph nodes from DO11.10 mice pooled and CD4 ⁺ T-cells isolated. Solution injected into tail veins of BALB/c mice day 0. CTLA4-Ig ip injected days 0, 2. PBLN cell suspensions plated, restimulated with OVA 4d. | UFCB + OVA induced proliferation of CD4 ⁺ T-cells, increased cytokine production. UFCB + OVA did not induce any effects in CD80/CD86-deficient mice. UFCB-induced airway inflammation is dose-dependent. |
| Reference: de Haar et al. (2008, 187128) Species: Mouse Cell Line: Myeloid dendritic cells (mDCs) | Ultrafine Carbon Black (UFCB) (Brunswick Chemicals; Amsterdam, The Netherlands) Particle Size: Diameter: 30-50nm | Route: Cell Culture Dose/Concentration: 25 µg/mL Time to Analysis: mDCs cultured from bone marrow. Exposed 18h. Cells isolated, stained for flow cytometry. | UFCB + OVA increased mDCs in the peribronchial lymph nodes, and their expressions of CD80, CD86, and MHC-11. |

| Reference: Dong et al. (2005, 088079) Species: Rat Gender: Male Strain: Brown-Norway (BN/CrlBR) Age: NR Weight: 200-225g | DEP: SRM 2975 (NIST, Gaithersburg, MD) OVA: Ovalbumin (Sigma ,St Louis, MO) Particle Size: 0.5 μ m (MMAD) | Route: Inhalation Dose/Concentration: DEP: 20.6 \pm 2.7 mg/m ³ OVA 40.5 \pm 6.3mg/m ³ Time to Analysis: 4 h/d for 5 days + OVA 30 min/d 1 x wk on days 8,15 & 29. Sacrificed on days 9 or 30. | <p>Lung Inflammation/Injury: Both the BAL proteins and inflammatory cell counts for DEP exposure alone were not different from those of the air exposed control, suggesting that DEP exposure did not cause lung injury at 9 or 30 days post-exposure. OVA exposure caused significant increases in neutrophils, lymphocytes, eosinophils, albumin and LDH activity in the lung after two exposures. DEP did show a strong effect on OVA-induced inflammatory responses.</p> <p>Alveolar Macrophage (AM) function: OVA exposure resulted in an increase in NO levels in the acellular BAL fluid and AM conditioned media. This increase was significantly attenuated in rats exposed to DEP. DEP exposure had no significant effect on the production of IL-10 or IL-12 by AM recovered from rats 9 and 30 days post exposure. In contrast, OVA sensitization elevated both IL-10 and IL-12 secretion by AM at both time points.</p> <p>Lymphocyte population and cytokine production: DEP exposure was found to increase the numbers of total lymphocytes, T cells and their CD4 + and CD8 + subsets in LDLN. OVA exposure also significantly increased these cell counts on days 9 and 30. DEP + OVA exposure showed a significant reduction in total lymphocytes, T cells, CD4 + and CD8 + subsets on day 30. Levels of IL-4 and IFN-γ in lymphocyte conditioned media were below detection limit of the ELISA kits.</p> <p>Intracellular GSH levels in AM and Lymphocytes: DEP exposure alone slightly decrease GSH levels in AM, but markedly reduced GSH concentration in lymphocytes on days 9 and 30. OVA exposure significantly decreased intracellular GSH in both cell types. Combined exposure showed AM and lymphocytes to have depleted intracellular GSH.</p> <p>OVA specific IgE and IgG levels in serum: In all samples collected on day 9, both serum IgG and IgE levels were under the detection limits. On day 30, no measureable IgE levels were found. The OVA exposure, however, resulted in elevated IgE levels, and was enhanced in rats preexposed to DEP. IgE and IgG levels for DEP + OVA was two times higher than OVA alone indicating that DEP has an adjuvant effect on the production of IgG and IgE.</p> <p>Effects of DEP and OVA on Lung iNOS expression: AM from various exposure groups did not stain for iNOS. 1 rat at day 9 from the combined DEP + OVA group showed a slightly positive iNOS staining. On day 30, 2 of 5 rats from combined exposure group and 1 from the OVA group showed a positive airway staining.</p> |

| Reference: Dong et al. (2005, 088083) Species: Rat Gender: Male Strain: Brown-Norway (BN/CrIBR) Age: NR Weight: 200-225g | DEP: SRM 2975 Diesel Exhaust Particles (NIST) OVA: Ovalbumin (Sigma Chemical Company, St Louis, MO) Particle Size: 0.5 μ m (MMAD) | Route: Nose-only Directed Flow Inhalation Dose/Concentration: DEP 22.7 \pm 2.5 mg/m ³ OVA 42.3 \pm 5.7mg/m ³ Time to Analysis: Day 1, 8, 15: OVA exposure 30min/day Days 24-28: DEP exposure 4h/day Day 29: OVA challenge Day 30: Whole-body plethysmography Day 31: Sacrifice | <p>Effect of DEP on OVA induced allergic responses: DEP exposure had a synergistic effect with OVA on inducing airway hyper-responsiveness (AHR) in rats. DEP alone had no effect on IgG production. Levels of OVA-specific IgG and IgE increased in OVA+DEP exposure. This indicates that DEP pre-exposure augments the immune response of rats to OVA in the production of allergen specific IgG and IgE.</p> <p>Effect of DEP on OVA induced cell differentiation: Neither DEP, OVA nor the combination induced elevated levels of LDH activity or albumin content, indicating that the exposure protocols did not cause significant lung injury. DEP alone induced moderate but significant increase of neutrophil numbers. OVA exposure induced a greater infiltration of neutrophils than DEP, and infiltration of eosinophils and lymphocytes. OVA-induced eosinophil count markedly increased with DEP exposure. Total lymphocytes, T cells, and their CD4+ and CD8+ subsets in LDLN from rats sensitized and challenged by OVA were significantly higher than those of air-exposed non sensitized rats. DEP+OVA exposure resulted in substantial increase in T cells compared to OVA alone.</p> <p>Effect of DEP on OVA-induced oxidant generation and GSH depletion: Exposure to DEP or OVA alone had no effect on ROS production by AM. Substantial elevation seen in ROS for the DEP+OVA exposed group. Both OVA and DEP exposures resulted in an increased presence of NO in the acellular BAL fluid and in AM conditioned media; OVA+DEP exposure further increased these levels. The ATII cells from OVA exposed rats exhibited a higher percentage of cells that produce NO and superoxide than air exposed, non sensitized rats. DEP and OVA exposure resulted in a significant increase in the percentage of cells that produce NO and superoxide over the control.</p> <p>iNOS expression: Immunohistological analysis in lung tissues showed no AM staining in any group. Airway epithelium was found to be positive in all 5 rats from the DEP+OVA group and 3 of 5 rats from single exposure of DEP or OVA and 2 of 5 in air only exposed rats. iNOS expression was significantly higher in ATII cells isolated from rats exposed to combined DEP and OVA .</p> <p>GSH levels in AM and lymphocytes: Levels were slightly lowered by DEP or OVA exposure, though not statistically significant. DEP+OVA showed a significant reduction in GSH levels.</p> |

|--|--|---|--|
| Reference: Drela et al. (2006, 096352) Species: Mouse Gender: Male Strain: BALB/c Age: 6 wks Weight: NR | ASM: Air suspended PM from Upper Silesia (Poland) 1µg of ASM: Pb (1.136 ng) Cu (0.004 µg) Co (0.072 ng) Mn (0.406 ng) Fe (0.016 µg) Cd (0.154 ng) Cr (0.418 ng) Ni (0.238 ng) Particle Size: 0.3-10 µm | Route: Intraperitoneal Injection Dose/Concentration: 170mg ASM/kg of body weight Time to Analysis: One time exposure, sacrificed 72h post exposure | CD28 expression on thymocytes at different stages of development: ASM exposure accelerated thymocyte maturation but did not alter the expression of CD28 on peripheral CD4 and CD8 T cells isolated from lymph nodes. A slight but not statistically significant decrease in the expression of CD28 on spleen T cells from ASM animals was observed. Distribution of CD28(low) and CD28(high): Acute exposure to ASM resulted in the increase of CD28(low) and decrease of CD28 (high) thymocyte percentages in the total thymocyte population. The percentages of CD28 low and high thymocytes did not differ between intact and PBS controls. Acute ASM exposure resulted in the increase of the percentage of CD28(low) and the decrease of CD28(high) thymocytes in the CD3 low subset. The percentage of CD28 low and high positive thymocytes did not differ in CD3 high thymocyte subset. Natural regulatory CD4+ CD25+ T cells in the thymus: The development of thymic natural regulatory cells was unaffected by ASM. Proliferation of splenocytes and lymph node lymphocytes: Decreased proliferative responses were evident in splenocytes from ASM-exposed animals when cells were stimulated with low but not high levels of anti-CD3 mAb. In contrast, lymph node lymphocytes from ASM treated mice had increased proliferative responses independent of anti-CD3 concentration. Both CD4+ and CD8+ T cells from ASM treated mice proliferated more vigorously than from controls. Almost all CD8+ T cells from ASM mice were induced to proliferate. |
| Reference: Dybing et al. (2004, 097545) Species: Mouse Gender: NR Strain: BALB/cA Age: NR Weight: NR Assay: PLN, ELISA | UP: Urban ambient particles collected in 5 different sites (Amsterdam, Lodz, Oslo, Rome, Dutch seaside) during four-week periods in spring, summer, winter seasons from March 2001 to March 2004. DEP as reference std: SRM 1650 (NIST) OVA: Ovalbumin (Sigma Chemical, St. Louis, MO) Particle Size: UP: PM ₁₀ and PM _{2.5} | Route: Injection in hind foot pad Dose/Concentration: UP: 100 µg- 200 µg DEP: 50 µg OVA: 50 µg Time to Analysis: PLN assay: Day 0: 1 exposure to OVA alone, OVA w/particles, particles alone. Day 6: Lymph nodes harvested Day 21: 1 OVA w/o particles exposure Day 26: Antibody assay | Allergy screening: All samples were immunostimulatory in the popliteal lymph node assay; activity was weak in the absence of OVA but statistically significant when injected with OVA, indicating an adjuvant effect. Particle adjuvancy was further demonstrated via significant enhancement of OVA-specific antibody responses. All ambient particle fractions from all seasons increased IgG1. Except for a few coarse samples, all fractions significantly increased IgE. All fine fractions and some coarse fractions significantly increased IgG2a, indicating that most particles could exert both Th1 and Th2 adjuvancy. In general, fine particles demonstrated stronger adjuvant activity than coarse in a pair-wise comparison of coarse and fine particles from the same location. |
| Reference: Dybing, et al. (2004, 097545) Species: Rat Cell Lines: Primary rat type 2 cells, rat alveolar macrophages Use: Inflammatory screening | UP: Urban ambient particles collected in 5 different sites (Amsterdam, Lodz, Oslo, Rome, Dutch seaside) during four-week periods in spring, summer, winter seasons from March 2001 to March 2004. DEP: SRM 2975 (NIST) OVA: Ovalbumin (Sigma Chemical, St. Louis, MO) Particle Size: PM ₁₀ and PM _{2.5} | Route: Cell Culture Dose/Concentration: 0 – 50 µg/ml Time to Analysis: 20h | Inflammation screening: The coarse fractions were more potent than the fine fractions. Among the samples, the overall effects of the coarse fractions on the cells were dependent on the site of collection. High MIP-2 levels were found using particles from some spring collections. Coarse particles collected in summer demonstrated the highest potency, and samples collected during winter proved to be less potent but seasonal variation was not obvious for all sites. Only minor responses were observed using fine fractions from urban sites. |

| Reference: Farraj et al. (2006, 141730) Species: Mouse Gender: Male Strain: BALB/c Age: 6 weeks Weight: NR | DEP: SRM 2975 NIST OVA: Ovalbumin Anti-p75: Rabbit anti-mouse p75 neurotrophin receptor polyclonal antibody (Chemicon, Temecula, CA) Anti-trkA: anti-mouse trkA NGF receptor antibody (Santa Cruz, Santa Cruz, CA) Particle Size: DEP: 1.47 μm (MMAD), 2.75 GSD | Route: Nose-only Inhalation Dose/Concentration: DEP: 1.78 to 2.18 mg/m ³ Anti-p75: 50 μl Anti-trkA: 50 μl OVA injection: 20 μg MCH: 0, 16, 32, 64 mg/ml Time to Analysis: On day 0: ip injection of 20 μg OVA Day 14: intranasal instillation of 50 μl anti-p75 or anti-trkA Day 14, 1-h after 1st exposure: challenged with OVA aerosol for 1h followed by a h exposure to DEP 24 h after DEP exposure: MCH challenge | Airways responsiveness: No significant differences in avg baseline Penh values of any treatment groups. Vehicle sensitized mice: exposure to DEP, anti-p75 or anti-trkA had no effect on MCH-induced Penh values. OVA-sensitized DEP-exposed: seen increase of Penh values. Administration of anti-p75 or anti-trkA to OVA sensitized mice reversed DEP induced Penh increases. Lung function in ventilated mice: Compared to vehicle sensitized mice, central airway resistance (R_n) increased 62% in OVA sensitized mice was not a significant increase. OVA-sensitized DEP-exposed mice, anti-p75 decreased central airway resistance (R_n) and anti-trkA did not significantly alter R_n , though R_n response for anti-p75 was significantly less than anti-trkA response, Constant phase model parameter of tissue elastance not significantly affected by any treatments or by increasing MCH dose, indicating development of significant regional ventilation inhomogeneity during bronchoconstriction. Airway pathology: OVA-sensitized mice had small increases in intraepithelial mucus compared to vehicle-sensitized mice. DEP exposure did not enhance severity of OVA-induced airway pathology. Anti-p75 or anti-trkA administration did not influence airway morphology. BAL cells: Vehicle-sensitized DEP-exposed mice had significantly enhanced macrophage numbers by 92% compared to air-exposed, vehicle-sensitized mice. Anti-p75 or Anti-trkA administration significantly suppressed DEP-induced macrophage increase to levels similar to air-exposed, vehicle-sensitized group. DEP co exposure significantly decreased number of macrophages in OVA-sensitized mice to control levels. Anti-trkA or anti-p75 had no effect in OVA-sensitized, DEP-exposed. Eosinophil number greater in OVA-sensitized DEP-exposed mice than in vehicle-sensitized air-exposed mice. No significant effects of DEP exposure on neutrophils from vehicle- or OVA-sensitized mice. Cytokines: <u>IL4:</u> OVA-sensitized DEP-exposed had five-fold increase over vehicle-sensitized, air-exposed mice and anti-p75 or anti-trkA significantly inhibited the DEP-induced increase. <u>IL5, IL13:</u> OVA-sensitized DEP-exposed had no significant change. Anti-p75 or anti-trkA administration had no significant effect. Serum IgE: OVA sensitized mice had a 10 fold increase in IgE levels for air and DEP exposed mice. Anti-p75, anti-trkA treatment did not cause significant effects on IgE levels. |

| Reference: Farraj et al. (2006, 189804) Species: Mouse Gender: Male Strains: C57/Bl6 Age: 6wks | DEP: SRM 2975 collected from diesel-powered industrial forklift filter (NIST) OVA: Ovalbumin Anti-p75: Rabbit anti-mouse p75 neurotrophin receptor polyclonal antibody Particle Size: 1.47 (MMAD), 2.75 (GSD) | Route: Nose-only Inhalation Dose/Concentration: DEP: 0.87 mg/m ³ MCH: 0, 16, 32, 64 mg/ml OVA: 20 µg ip Anti-p75: 50 µl Time to Analysis: Day 0: OVA in gel vehicle, ip Day 14: anti-p75 exposure, intranasal instillation 1h post anti-p75 exposure, OVA aerosol challenge for 1h 1h post OVA challenge: DEP exposure for 5h 48h post DEP exposure: MCH challenge | Airway responsiveness: No significant differences in average Penh values among any vehicle control groups. No significant differences in treatment groups in OVA-sensitized mice at baseline 0, 16, or 32 mg/mL of MCH. At 64 mg/mL MCH, OVA-sensitized, DEP-exposed mice had a 22% increase in Penh compared to vehicle mice, and a 68% increase compared to vehicle-sensitized, air-exposed mice. Instillation of anti-p75 inhibited the DEP induced increased Penh. BAL cells: DEP exposure in vehicle-sensitized mice significantly increased macrophages by 161% compared to air-exposed, vehicle-sensitized mice, while OVA-sensitized mice had 69% increase. Anti-p75 administration significantly suppressed DEP-induced macrophage increase in vehicle-sensitized mice. No significant effects of DEP exposure or anti-p75 treatment in OVA-allergic mice. OVA-sensitized air-exposed mice had a several hundred fold increase in the number of eosinophils. No significant effects of DEP exposure or anti-p75 treatment on eosinophils from OVA-sensitized mice. OVA-exposure or DEP-exposure had no significant effects on neutrophil or lymphocyte number. BAL cytokines: No significant effects of DEP alone or with OVA on IL-4, IL-5, or IL-13. Serum IgE: OVA sensitization in the presence or absence of DEP or anti-p75 caused at least a 3 fold increase in IgE levels. No significant effects of DEP or anti-p75 treatment on IgE levels. |
| Reference: Finkelman et al. (2004, 096572) Species: Mouse Gender: Female Strains: BALB/c and C57BL/6 Age: 2-4 m | DEP: 4JB1 type; Isuzu Automobile, Tokyo, Japan Particle Size: 2 µm MMAD | Route: Two groups: Group1: 1 ip injection of 2 mg of DEP. Group 2: daily ip injections of 2mg of DEP Dose/Concentration: 2 mg Time to Analysis: 2-96h | Serum Cytokines: Mice in group 1 demonstrated an increase in serum IL-6 production but no increase in IL-4 or IL-2 production. IFN- α levels were decreased in group 2. TNF production was not affected. Spleen Cytokines: When injected before LPS, DEP had little effect on the LPS-induced TNF- α and IL-6 response, but resulted in a minor suppression of INF- α and IL-10. DEP LPS-induced increase in INF- α mRNA responses in spleen cells. DEP caused a dose related suppression of LPS stimulated INF- α . DEP had little or no effect on the percentage of NK or NKT cells in the spleen and inhibited LPS-induced IFN- α production by NK and NKT. DEP failed to inhibit the IFN- α response by anti-CD3 mAb-activated NKT cells. Oxidant activity was not responsible for DEP inhibition of LPS-induced IFN- α production. |
| Reference: Fujimaki and Kurokawa (2004, 189578) Species: Mouse Gender: Male Strains: BALB/c Age: 4 wks Cell Types: Cervical lymph-node (CLN) cells | DE \pm particles: Comparison of exposure to DE including particles and exposure to particle-filtered DE All mice were injected with sugi basic protein (SBP), a cedar pollen allergen before exposure to DE Particle Size: 0.4 µm MMAD | Route: Whole-body Exposure Dose/Concentration: Exposure to: 0, 1.0 mg/m ³ or 1.0mg/m ³ DE gas only (0.04 mg/m ³ PM) Time to Analysis: Exposure for 12h daily for 5wks. Days 14 and 35 challenge with SBP intranasally. Evaluation is 24 and 48h after final SBP injection. | CLN response: Exposure to DE or DE gas did not affect B1 lymphocyte subpopulations of CLN. Culture supernatants of CLN cells from DE exposed/SBP immunized mice showed significant increase in MCP-1 at 24 and 48 h. Exposure to DE or DE gas significantly increased the amount of TARC and MIP-1 α in CLN cells from SBP-immunized mice at 48 h. Composition of DE and DE gas: DE: 12.09 \pm 0.15 NO _x , 1.99 \pm 0.02 NO ₂ , 10.02 \pm 0.12 NO, 0.18 \pm 0.002 SO ₂ and 1769.2 \pm 13.2 CO ₂ (all in ppm). DE gas: 11.93 \pm 0.13 NO _x , 2.93 \pm 0.06 NO ₂ , 8.91 \pm 0.09 NO, 0.11 \pm 0.003 SO ₂ and 1838.8 \pm 15.3 CO ₂ (all in ppm) |

| Reference: Fujimaki et al. (2005, 156456) Species: Mouse Gender: Male Strains: C57BL/6 Age: 4 wks Cell Types CLN (lymph node) and Plasma cells | DE generated by 4 cyl 2.74 l Isuzu diesel DE gas = DE filtered to remove particles Composition of Diesel Exhaust: DE DEP: 1.01 mg/m ³ 1796ppm CO ₂ 12.09ppm NO _x 0.18 ppm SO ₂ Composition of filtered DE Gas: DEP: 0.04 mg/m ³ 1839ppm CO ₂ 11.93ppm NO _x 0.11 ppm SO ₂ Sugi Basic Protein (SBP)- allergen Particle Size Average diameter of DEP 0.4 μm | Route: Whole-body Exposure Chamber Dose/Concentration: 1.0mg DEP/m ³ or 1.0mg DEP/m ³ DE gas Time to Analysis: Exposure for 12h daily for 5wks. All mice were injected IP with 100 μg SBP before exposure to gas or DE and again received 50 μg SBP intranasally on days 14 and 35. Evaluation is 1d after final SBP-immunization (mice are euthanized and CLN and blood samples are collected) | CLN: Exposure to DE and gas led to a decrease in total number of CLN cells and percentage of CD4+ and TCR-B levels. Cell proliferation response to SBP was higher in gas-exposed mice than in the control group. The production of MCP-1 increased in CLN cells when stimulated with SBP (in vitro) but the difference was not significant at 24 and 48h. SBP-stimulated cells in gas-exposed mice showed greatly enhanced MIP-1α production at 24 and 48 h. Exposure to gas increased the amount of TARC in the culture supernatants of CLN cells. PLASMA: Exposure to DE or gas significantly decreased the anti-SBP IgG1 antibody titers and increased increased the anti-SBP IgG2a antibody titers in mouse plasma. |
| Reference: Fujimoto et al. (2005, 096556) Species: Mouse Gender: Female 1st day of pregnancy) Strains: Slc: IRC Cell Types Fetal Cells/ RNA Spleen Cells | DEP: generated by a 2369-cc diesel engine operated at 1050 rpm and 80% load with commercial light oil Particle Size: 0.4 μm MMAD | Route: Whole-body Inhalation Chambers Dose/Concentration: 0.3, 1.0 and 3.0 mg DEP/m ³ (Groups 1,2,3) Time to Analysis: Exposure began at 2d postcoitum and was continued until 13d postcoitum. Exposure time was 12h daily for 7d/wk. Pregnant females were sacrificed 14d postcoitum. | mRNA Expression in Placentas: In groups exposed to DE, the expression of CYP1A1 mRNA decreased to undetectable levels during placental absorption and INF-α was increased. Levels of CYP1A1 mRNA in normal placentas from DE-exposed mice were unchanged. mRNA levels of inflammatory cytokines IL-2, IL-5, IL-12α, IL-12B and GM-CSF increased in placentas of mice exposed to DE. |
| Reference: Gao et al. (2004, 087950) Species: Human Cell Line: Lung fibroblasts infected with <i>Mycoplasma fermentans</i> | ROFA: collected near a power plant in FL burning low sulfur # 6 oil. (PM from Dusseldorf, volcanic ash for Mt. St. Helens, PM from Utah used to compare against ROFA in one experiment) Particle Size: NR | Route: Cell Culture Dose/Concentration: Cells were seeded into 6-well plates (3-4.5X10 ⁵ cells/3mL/well) or 24-well plates (0.6-1 X10 ⁵ cells/1.0 mL/well) 3, 10, 20, 40, 50 μg/ml Time to Analysis: 24, 48h | Cytokines: ROFA exposure in combination with <i>Mycoplasma fermentans</i> infection synergistically amplifies the induction of IL-6 production in human lung fibroblasts (HLF). PM from the other sources has little synergistic effect on IL-6 release. Exposing HLF cells to <i>M. fermentans</i> derived macrophage activating lipopeptide-2 (MALP-2) and ROFA has the same synergistic effect as <i>M. fermentans</i> infection and ROFA. MALP-2 and ROFA extract have a similar synergistic effect that requires more time to appear. ROFA contains high levels of V, Ni, Fe and Cu. Exposure of HLF to NiSO ₄ alone and NiSO ₄ with MALP-2 produced 10 and 50 fold increases, respectively, in IL-6 production. Exposure of HLF to CuSO ₄ , VOSO ₄ and Na ₂ VO ₄ , with and without the presence of MALP-2, did not produce as dramatic results as seen with Ni. The action of NiSO ₄ and MALP-2 on IL-6 production was found to be dose dependent. |

| Reference: Gavett et al. (2003, 053153) Species: Mouse Gender: Female Strain: BALB/c Age: 7wks | <p>PM_{2.5} from the German cities of Hettstedt or Zerbst</p> <p>PM Composition: samples from Hettstedt have several-fold higher levels of zinc, magnesium, lead, copper and cadmium than samples from Zerbst.</p> <p>Particle Size: PM_{2.5}</p> | <p>Route: Oropharyngeal Aspirations</p> <p>Dose/Concentration: 50-100μg PM in 50 μL saline</p> <p>Time to Analysis: Mice were exposed to one dose of 100 μg BAL 18h after exposure.</p> <p>Sensitization Model: Mice were exposed to 50 μg PM 2h before being sensitized with 10 μg OVA, repeated two days later. On day 14- all mice were challenged with 20 μg OVA.</p> <p>Parameters measured on days 2 and 7 after FINAL exposure to OVA.</p> <p>Challenge Model: Mice were sensitized IP with 20 μg OVA or adjuvant only. 14d later mice were exposed to 100 μg PM_{2.5} followed 2h later by 20 μg OVA. Parameters measured on days 2 and 7 after FINAL exposure to OVA.</p> | <p>BAL Analysis: Hettstedt PM significantly increased BAL protein and NAG levels. Zerbst PM did not. Mice exposed to Zerbst had lower levels of LDH than control groups. Hettstedt exposed mice had increased levels of IL-1B, IL-6 and MIP-2 in comparison to control and to mice exposed to Zerbst PM. PM_{2.5} at a dose of 100 μg was not found to be toxic, therefore used for subsequent studies.</p> <p>Airway Responsiveness (PenH): In allergic mice tested immediately after exposure, Hettstedt PM increased PenH 190% compared to baseline, Zerbst increased PenH by 120% and the Control increased by 44%... Two days after OVA challenge, no differences in non-allergic mice from either group. In allergic mice, Hettstedt PM still caused a significant response to Mch responsiveness, Zerbst none. No effects on day seven.</p> <p>IgE Levels: Serum collected on day 2 showed antigen-specific IgE was increased by Hettstedt PM_{2.5} in both the sensitization and challenge phases when compared to the control and exposure to Zerbst. Day 7 serum indicated no effect.</p> <p>BAL Cell Counts: In non-allergic mice both Hettstedt and Zerbst PM increased BAL neutrophil numbers (3-fold; not statistically significant) and in allergic mice, only Hettstedt PM significantly increased neutrophil count. Eosinophil numbers were increased only in allergic mice exposed to Hettstedt PM. Lymphocyte numbers were not different among groups.</p> <p>BAL Lung Injury: At 2 days after both Hettstedt and Zerbst PM administered in allergic mice caused significant increases in protein, LDH and NAG compared to the non-allergic groups. Both PMs caused an increase in LDH in allergic mice compared to the allergic control, but only Hettstedt caused an increase NAG in allergic mice compared to control. At 7 days no effect.</p> <p>BAL Cytokines: Allergic mice had increased levels of IL-4, IL-5 and IL-13 compared to non-allergic mice (at 2 days after). IL-5 was significantly increased by exposure to either PM in allergic mice compared to non-allergic mice. Exposure to either PM caused an increase in TNF-α and IFN-γ (by 6-8 fold) in allergic mice, there was also an increase in these inflammatory cytokines in the non-allergic group but was not statistically significant. No significant effects were observed in animals that underwent the sensitization protocol alone for any measurement or endpoint.</p> |
| Reference: Gowdy et al. (2008, 097226) Species: Mouse Gender: Female Strain: BALB/c Age: ~ 12-14wks Weight: 17-20g | <p>DEP (30kW (40hp) 4-cylinder Deutz BF4M1008 diesel engine, steady state, 20% full load) (Low dose: 21% O₂, 0.4wt ratio OC/EC; High dose: 20.7% O₂, 0.4wt ratio OC/EC) (CO, NO_x, SO₂)</p> <p>Particle Size: Diameter: ~ 240nm</p> | <p>Route: Inhalation Exposure Chamber</p> <p>Dose/Concentration: Low- 514 \pm 3 μg/m³, High- 2026 \pm 38 μg/m³</p> <p>Time to Analysis: Exposed 4h/d, 1 or 5d (consecutive). Necropsied immediately or 18h postexposure.</p> | <p>Inflammation: Neutrophils and lung injury dose-dependently increased. ICAM-1 increased immediately after both exposures and after 18h postexposure in the low dose.</p> <p>Cytokines: After 1d exposure, IFN-α and TNF-α increased immediately at both doses and the high dose, respectively. Immediately after 5d exposure TNF-α and IFN-α increased at both concentrations and IL-6 increased at the low dose. At 18h postexposure IL-6 and IFN-α increased at both doses, TNF-α and IL-13 increased at the low dose, and MIP-2 dose-dependently increased.</p> <p>CCSP, Surfactants: CCSP decreased. SP-A and SP-D decreases were only significant after 5d exposure, 18h postexposure.</p> |

| Reference: Hamada et al. (2007, 091235) Species: Mouse Gender: Female (Pregnant close to parturition) Strain: BALB/c Use: Pregnant mice were exposed and offspring were analyzed | ROFA ROFA was obtained from a precipitator until of a local power plant. Composition of ROFA (in µg/mL): 341.2 Ni, 323.4 V, 232.2 Zn, 18.3 Co, 15.8 Mn, 8.4 Ca, 6.7 Cu, 6.1 Sr, 5.0 mg, 0.9 Sb, and 0.6 Cd. Particle Size: NR | Route: Nebulized ROFA lechate Dose/Concentration: 50mg/mL dilution Time to Analysis: Pregnant mice exposed to nebulized ROFA leachate for 30 min/day at days 14, 16 and 18 of pregnancy. Newborns received a single injection (ip) of OVA(5 µg) + alum (1mg) at day followed by exposure to: 1. aerosolized OVA days 12, 13 and 14 (2-week old protocol) OR 2. aerosolized OVA days 32, 33 and 34 (5wk old protocol) Analysis 48h after final allergen exposure | Susceptibility to Asthma: Exposure of mother to PBS aerosols during pregnancy did not result in prominent asthma features in young. The offspring of the ROFA mothers revealed increasing AHR and elevated numbers of eosinophils in the BAL fluid. Similar results were seen in both the 2-week and 5-week old groups. IgE Levels: Histopathology revealed prominent inflammation in the lungs of the ROFA neonates and increased allergen-specific IgE and IgG1 levels in the 5-week group. Maternal Influence: Breast milk was not shown to be responsible for the increased susceptibility to allergy seen in offspring. IL-4 and IFN-γ: IL-4 and IFN-γ levels in maternal mice showed no difference between PBS exposed or ROFA exposed mice. Cultured spleen cells from mice born of ROFA-exposed mothers showed either increased or similar levels of IL-4 and decreased production of IFN-γ causing an increase in the ratio of IL-4/IFN-γ indicating greater susceptibility to develop Th2- allergic response. Eosinophils: Exposure of mothers to Ni levels similar to those found in ROFA had no appreciable effect on BAL eosinophil. |
| Reference: Hao et al. (2003, 096565) Species: Mouse Gender: Female Strain: BALB/c Age: 6-7 weeks | DEP DEP collected from a 4-cylinder diesel engine under a 10-torque load. Particle Size: NR | Route: Nebulization Dose/Concentration: 2 mg/m ³ DEP Time to Analysis: Mild Sensitization- Mice receive IP OVA alum and are challenge with aerosolized OVA with and without DEPs. Mice sacrificed d19. Postchallenge Model- DEPs are delivered to mice sensitized by IP OVA and alum. Mice sacrificed d23. Transgenic Mice: Mice exposed to nebulized saline or DEPs for 1-h daily for 3 days. Mice sacrificed d5. | Mild Sensitization: Exposure of previously OVA sensitized mice to aerosolized DEP and OVA did not affect OVA-specific IgE production, BAL eosinophilia or methacholine-induced AHR. Aerosolized particles induced inflammation and increased MBP deposition and MBP positive eosinophils in the mucosa. IL-5 Transgenic: Exposure to aerosolized DEP did not change BAL cytokine levels, but did increase AHR and BAL cell count. Classic Sensitization, Post-Challenge: Did not lead to a discernable increase in OVA-induced AHR. DEP treatment was associated with increased airway inflammation and mucin production in larger and intermediary airways. |
| Reference: Harkema et al. (2004, 056842) Species: Rat Gender: Male Strain: F344, BN Age: 10-12wks Weight: NR | CAPs (Detroit; July-Sept. 2000; Harvard Ambient Fine Particle Concentrator) Particle Size: Diameter: 2.5 µm | Route: Inhalation Exposure Chamber. IT Instillation. Dose/Concentration: 4d concentration: 676 ± 288 µg/m ³ , 5d concentration: 313 ± 119 µg/m ³ , July concentration: 16-185 µg/m ³ , September concentration: 81-755 µg/m ³ ; IT Instillation- 200 µL (soluble and insoluble) Time to Analysis: F344 rats sensitized to endotoxin, BN rats to OVA. Exposed 10h/d 1, 4, 5d (consecutive). Another group of rats IT instilled. Both groups killed 24h postexposure. | The retention of PM in the airways was enhanced by allergic sensitization. Recovery of anthropogenic trace elements was greatest for CAPs-exposed rats. Temporal increases in these elements were associated with eosinophil influx, BALF protein content and increased airway mucosubstances. A mild pulmonary neutrophilic inflammation was observed in rats instilled with the insoluble fraction but instillation of total, soluble or insoluble PM _{2.5} in allergic rats did not result in differential effects. |

| Reference: Harrod et al. (2003, 097046) Species: Mouse Gender: NR Strains: C57BL/6 Age: 8-10wks Use: Infected with RSV | DEE: Diesel Engine Emissions generated from a 5.9-liter turbo diesel engine fueled by Number 2 fuel. DEE Composition: NOx: 2.0-43.3ppm CO: 0.94-29.0ppm SO ₂ : 8.3-364.9ppb Particle Size: for high & low level: 0.1-0.2 μ m (MMAD) | Route: DEE: Whole-body Inhalation RSV: IT administration Dose/Concentration: DEE: 38.8 μ g/m ³ (low level) or 10027 μ g/m ³ (high level) RSV: 100 μ l (10 ⁶ pfu) Time to Analysis: 6 h/d for 7 d. After the final 6h exposure period mice were infected with RSV. Parameters measured 4d post infection | <p>Viral Gene Expression: For air + RSV, RSV-F gene expression was not apparent but RSV-G gene expression was detectable at very low levels. In DEE + RSV (for high and low levels), RSV-F and -G were markedly elevated. β-Actin mRNA levels not changed in DEE-exposed compared to air-treated. DEE + RSV for high and low levels show 10- to 20- fold induction of RSV-G mRNA levels as compared to air + RSV.</p> <p>Cell numbers in BALF: Uninfected low-level DEE did not induce statistically significant increase in cell numbers as compared to air + RSV. High level DEE + RSV caused increase as compared to air + RSV. Uninfected high-level DEE had increase as compared to uninfected air group. For all groups, alveolar macrophages were predominant cell type and no substantial changes in infiltrating cell populations by exposure to DEE were noted.</p> <p>Lung inflammation & Airway Epithelial Morphology: Lung sections from air- or DEE-exposed, uninfected did not exhibit any observable change. Low level DEE + RSV had increased inflammatory cell infiltration in peribronchial regions and loss of normal cuboidal appearance of Clara cells as compared to air + RSV. High level DEE + RSV had more apparent lung-inflammation, especially surrounding bronchi and bronchioles, and increased appearance of pseudostratified, columnar epithelial cell morphology and apparent airway epithelial cell sloughing as compared to low level DEE + RSV, indicating dose-related increase in lung histopathology to RSV infection by prior DEE exposure.</p> <p>Inflammatory Mediators: TNF-α and IFN-α were significantly increased in RSV-infected mice exposed to low or high level DEE and not increased in RSV-infected mice exposed to air. TNF-α levels elevated to similar levels for low and high level DEE + RSV. IFN-α exhibited more dose-related increase with higher levels in high level DEE + RSV versus low level DEE + RSV.</p> <p>Mucous Cell Metaplasia: DEE exposure in uninfected was not altered. Mucous metaplasia was increased in epithelium of RSV-infected mice when exposed to DEE in a dose-dependent manner. Following high level DEE + RSV, mucous staining of airway epithelial cells in more distal airways was occasionally observed.</p> <p>CCSP Production in Airway Epithelium: DEE alone did not have an effect CCSP-producing cells, or Clara cells, decreased in Low DEE + RSV and further decreased in high level DEE + RSV in large and terminal airways.</p> <p>Surfactant Protein B: proSP-B staining post RSV alone shows now discernible decrease when compared to uninfected. Staining levels in alveolar lung regions decreased when exposed to low level DEE + RSV, and further decreased in high level DEE + RSV. Staining in airway epithelium following high level DEE + RSV diminished when compared to RSV alone or low level DEE + RSV.</p> <p>SP-A: In alveolar type II cells and airway epithelial cells for untreated and air + RSV, no discernible changes in levels. Prior exposure to low or high level DEE decreased SP-A staining in alveolar type II cells and airways epithelial cells during RSV infection.</p> |

| Reference: Harrod et al. (2005, 088144) Species: Mouse Gender: Male Strain: C57B1/6 Age: 10-12wks Weight: NR | DEE (2 2000 model 5.9-1 Cummins ISB turbo diesel engines, No. 2 certification diesel fuel) Particle Size: NR | Route: Exposure Chamber Dose/Concentration: Low- 30 $\mu\text{g}/\text{m}^3$ PM, Mid-Low- 100 $\mu\text{g}/\text{m}^3$ PM, Mid-High- 300 $\mu\text{g}/\text{m}^3$ PM, High- 1000 $\mu\text{g}/\text{m}^3$ PM Time to Analysis: Exposed 6h/d, 7d/wk, 1wk or 6m. 1wk exposure repeated on separate occasion. Immediately after exposure, mice anesthetized, IT instilled with <i>Pseudomonas aeruginosa</i> . | Bacterial Clearance: Lung bacterial clearance was decreased at all levels after 1wk exposure and was concentration-dependent 18h postinfection. Bacterial clearance was not affected at 6m and bacterial counts were higher. Inflammation, Particle Deposition: Lung inflammation and histopathology were increased in all exposure groups postinfection. All exposure groups possessed particle-laden macrophages. Higher doses had a concentration-dependent increase. Ciliated, Clara Cells, TTF-1: Generally, ciliated cells decreased with exposure dose, were more discernible in inflamed airways, and higher doses caused effects in small distal airways. Clara cells decreased equally at all exposures and were most notable in the distal airway epithelium. TTF-1 decreased postinfection. |
| Reference: Heidenfelder et al. (2009, 190026) Species: Rat Gender: Male Strain: Brown-Norway Age: 10-12wks Weight: NR | CAPs (Grand Rapids, MI; July) Particle Size: Diameter: 0.1-2.5 μm | Route: Whole-body Inhalation Chamber Dose/Concentration: CAPs: $493 \pm 391 \mu\text{g}/\text{m}^3$; OC: $244 \pm 144 \mu\text{g}/\text{m}^3$, EC: $10 \pm 4 \mu\text{g}/\text{m}^3$, Sulfate: $79 \pm 131 \mu\text{g}/\text{m}^3$, Nitrate: $39 \pm 67 \mu\text{g}/\text{m}^3$, Ammonium: $39 \pm 59 \mu\text{g}/\text{m}^3$, Urban dust (Fe, Al, Ca, Si): $18 \pm 6 \mu\text{g}/\text{m}^3$ Time to Analysis: Sensitized to OVA 3d. Challenged with OVA or saline 2wks later for 3d. Exposed to CAPs 8h/d, 13d. OVA or saline challenge 9d after first challenge. Sacrificed 24h after last CAPs exposure. | CAPs enhanced the effects of OVA by causing differential expression in genes primarily involved in inflammation and airway remodeling. CAPs exposure alone had no effect on gene expression. CAPs + OVA also increased IgE, mucin glycoprotein, and BALF total protein, and caused a more severe bronchopneumonia, increased mucus cell metaplasia/hyperplasia and mucosubstances. |
| Reference: Hiramatsu et al. (2003, 155846) Species: Mouse Gender: Female Strains: BALB/c and C57BL/6 Age: 8wks Weight: 17-22g | DE -DE (generated by diesel engine and diluted with filtered clean air) Particle Size: NR | Route: Exposure Chamber Dose/Concentration: Low dose -0.1mg/m ³ Highdose - 3mg/m ³ Time to Analysis: 1 or 3 months (7 h/d , 5 d/wk) | Lung Histopathology: DEP-laden macrophages accumulated in the alveoli and peribronchial tissues in a dose- and duration-dependent manner in both strains. Lymphocytes and neutrophils increased in both strains, but were greatest in the BALB/c mice. BALF and Mac-1 Positive Cells: BALF formation in DEP-laden AMs was seen at the high dose group and was greater in the BALB/c mice. Mac-1 positive cells, a marker for phagocytic activation of the AMs, was observed in the high dose groups of both strains at 1 and 3 months, and in the low dose group at 1 month in BALB/c mice. Cytokine and iNOS mRNA expression: 1 month of exposure increased TNF- α , IL-12p40, IL-4 and IL-10 mRNA in a dose-dependent manner. IL-1B and iNOS decreased in a dose-dependent manner. IFN- γ mRNA expression increased in BALB/c mice and decreased in C57BL/6 mice. Similar results were seen at 3 months, except IL-4 and IFN- γ mRNA expression decreased in the BALB/c mice. In C57BL/6 mice, IL-4 and IL-10 mRNA increased at the low dose but decreased at the high dose. NF- κ B activation occurred after 1 week and 1 month DE exposure and was more prevalent in BALB/c mice. |

| Reference: Hiramatsu, (2005, 088285) Species: Mouse Gender: Female Strains: BALB/c Age: 8wks Weight: 17-22g | DE (generated by diesel engine and diluted with filtered clean air.) Mycobacterial Infection - <i>M. tuberculosis</i> (ATCC35812) Kuroko strain Particle Size: NR | Route: Exposure Chamber Dose/Concentration: Low DE dose – 0.1mg/m ³ High DE dose - 3mg/m ³ Mycobacterial infection: 5mL (nebulized) of a 10 ⁶ colony-forming units (CFU) suspension Time to Analysis: 1, 2 or 6m (7h/d, 5d/wk). 6 mice from each group infected on last day of DE exposure. CFU evaluation 7wks postinfection. | Histopathological observations: DEP-laden AMs and DEPs in the alveoli and peribronchial tissues increased in a time-dependent manner. DE-exposed mice had a greater number of mycobacterial lesions, which were disseminated. Lesions in the control mice had clear borders and consisted of epithelial cells and lymphocytes. Tubercle bacilli and DEPs coexisted in AMs. BALT was seen around DEPs in the 2 and 6-month exposure groups. Inflammation cells increased in a time-dependent manner with respect to DE exposure. Granulomatous lesions in lungs: 6-month DE-exposed mice had a significantly higher amount of gross lesions than the 6-month control mice. Mycobacterial burden: CFU in lungs were increased in DE-exposed animals but only the 6 month exposure resulted in statistically significant increases (a ~4-fold increase over control). CFU in spleen were not significantly altered by DE exposure. Cytokines and iNOS mRNA expression: Infected DE-exposed mice had time-dependent increases of TNF- α , IL-1B, IL-12p40, IFN- α and iNOS mRNAs compared to the infected control mice. IL-12 mRNA expression decreased in infected 6-month DE-exposed mice. |
| Reference: Ichinose, T. et al. (2003, 041525) Species: Mouse Gender: NR Strains: BALB/cAnN, ICR, and C3H/HeN Age: 6wks Weight: NR | DE: DE generated by 3059cc 4-cylinder diesel engine Der f: Crude extract of <i>D. farinae</i> Particle Size: DEP · Mass median aerodynamic diameter: 0.4 μ m | Route: Exposure Chamber; IT Instillation Dose/Concentration: 1. Air 2. DE only: 3.0mg/m ³ 3. Air + Der f: 1mg Der f 4. DE 3.0mg/m ³ + 1mg Der f Time to Analysis: DE: 8wks (12h/d, 7d/wk) Der f: 2wk intervals, 6wks Analyzed 3d after last instillation | Light microscopic observations: DE exposure caused the proliferation of nonciliated cells and epithelial cell hypertrophy. Soot-containing macrophages were found in the alveolar tissue spaces. Accumulated lymphocytes were present in the peribronchiolar lymphoid tissue. Inflammatory cells and soot-containing macrophages were found in the submucosal layer and the vessel interstitium of mice treated with DE + Der f in all strains. DE + Der f treated C3H/He mice had desquamated goblet cells. Eosinophil infiltration: DE treated C3H/He mice had a slight eosinophile infiltration in the submucosal layer. DE + Der f treated mice in all strains had a slight to moderate eosinophile infiltration. Lymphocyte accumulation: Lymphocytes significantly increased in all strains under the DE treatment as compared to the air + saline treatment, and further increased under the DE + Der f treatment. Goblet cell proliferation: Little proliferation was seen in all strains under the DE treatment. DE + Der f caused a significant increase in proliferation compared to air + Der f in ICR mice, but a significant decrease in C3H/He mice. Local cytokine and chemokine expression in lung tissue supernatant: DE + saline significantly increased MIP-1 α in all strains. MCP-1 also increased but not significantly. DE + Der f increased IL-5, RANTES, eotaxin, MCP-1 and MIP-1 α in all strains as compared with air + saline and air + Der f. IL-5 decreased in C3H/He mice treated with DE + Der f compared to air + Der f. IL-3 decreased in ICR and C3H/He mice compared to air + saline. Der f-specific immunoglobulin production in plasma: Increased production of IgG1 was statistically significant in ICR and C3H/He mice treated with DE + Der f as compared to air + Der f. IgE was low in all strains. |

| Reference: Ichinose et al. (2004, 180367) Species: Mouse Gender: NR Strains: BALB/c, ICR and C3H/He Age: 5wks Weight: NR | DEP: 2740cc 4-cylinder engine <i>D. farinae</i> : crude extract Particle Size: DEP - Mass median aerodynamic diameter of 0.4 μ m | Route: IT Instillation Dose/Concentration: 1. <i>D. farinae</i> : 1 μ m in PBS 2. <i>D. farinae</i> + DEP: 1 μ g in PBS + 50 μ g mg DEP Time to Analysis: 4 times at 2wk intervals. Mice examined 3wks after last instillation | Histological changes: Mice in all three strains treated with DEP + <i>D. farinae</i> had a significant recruitment of eosinophils, more proliferation of goblet cells, and more eosinophilic positive macrophages in the alveoli than mice treated with <i>D. farinae</i> alone. Local cytokine expression in lung tissue supernatant: DEP + <i>D. farinae</i> induced significant elevation of IL-5 in ICR and C3H/He mice as compared to <i>D. farinae</i> alone. Production levels of IL-4 and RANTES did not correlate with the manifestations of allergic airway inflammation induced by the <i>D. farinae</i> treatment with or without DEP. Cytokine expression in plasma: IL-5 in C3H/He mice treated with DEP + <i>D. farinae</i> was significantly higher than <i>D. farinae</i> alone. RANTES was unaffected by the DEP treatment in all strains. <i>D. farinae</i>-specific immunoglobulin production in plasma: The adjuvant effect of DEP on IgG1 production was observed in all three strains, with C3H/H3 being statistically significant. The production levels of IgG1 correlated with the manifestations of eosinophilic airway inflammation by both treatments. No adjuvant effect on IgE production was observed. |
| Reference: Inoue et al. (2006, 097815) Species: Mouse Gender: Male Strain: ICR Age: 6wks Weight: 29-33g | PM-OC: Urban PM, collected for 1 month during early summer, 2001 in Urawa city Saitama, Japan LPS Particle Size: < 2.0 μ m, 40mg/m ³ | Route: IT Instillation Dose/Concentration: Vehicle group: PBS PM-OC group: 4mg/kg of PM-OC LPS group: 2.5mg/kg of LPS PM-OC + LPS group: combined administration of PM-OC + LPS Time to Analysis: 24h after IT administration | Effects of PM-OC on LPS related lung inflammation: PM-OC alone did not significantly increase the infiltration of neutrophils, but LPS challenge showed a marked increase in the number of neutrophils compared with vehicle. Administration of LPS combined with PM-OC significantly increased the infiltration of neutrophils compared with LPS administration alone. Effects of PM-OC on histological changes in the lung: Combined treatment with PM-OC and LPS resulted in enhanced neutrophilic inflammation. Effects of PM-OC on pulmonary edema related to LPS: LPS group compared with vehicle group had a significant increase in lung water. The combined administration of PM-OC and LPS resulted in further increase in the lung water compared with LPS administration alone, however it was not statistically significant. Effects of PM-OC on protein expression IL-1β, MIP-1α, MCP-1 and KC: The concentrations of these molecules were below the detection limits in the PM-OC group. LPS treatment significantly increased the protein levels of these molecules compared with the vehicle treatment. In the PM-OC + LPS group all concentrations, particularly KC, were smaller than in the LPS group. |

| Reference: Inoue et al.(2006, 096720) Species: Mouse Gender: Male Strain: ICR Age: 6wks Weight: 29-33g | Carbon black (14 nm PrinteX 90; 56nm PrinteX 25; Degussa, Dusseldorf, Germany) Particle Size: 14nm - 300 m ² /g 56nm - 45m ² /g | Route: IT Instillation Dose/Concentration: Vehicle group: PBS at pH7.4 LPS group: 2.5mg/kg of LPS in vehicle Nanoparticle groups: 4 mg/kg carbon black nanoparticles (14nm or 56 nm) in vehicle LPS + nanoparticle group: combined administration of carbon black and LPS in vehicle Time to Analysis: 24h after IT administration | Effects of nanoparticles: Nanoparticles alone increased number of total cells and neutrophils, but not statistically significant. LPS exposure significantly increased numbers for both groups. Nanoparticles and/or LPS enhance pulmonary edema. Histological changes: Treatment with LPS + 14 nm nanoparticles markedly enhanced neutrophil sequestration into the lung parenchyma compared to LPS alone. LPS + 56 nm nanoparticles did not. Proinflammatory cytokine proteins: IL-1B level significantly greater for both LPS + nanoparticles groups. TNF-α was not significantly altered among the experimental groups. Chemokine proteins: Challenge with 14nm nanoparticles alone elevated the levels of all chemokines without significance except for KC. LPS alone and with both nanoparticle groups caused significant increases in all chemokines. . Formations of 8-OHdG in lung: LPS plus nanoparticles resulted in intensive expression 8-OHdG, strongest in LPS + 14nm nanoparticle Plasma coagulatory changes: PT - no change for any group. APTT - some change with LPS and LPS + nanoparticle groups, fibrinogen level significantly elevated after LPS and for LPS + 14nm nanoparticle. APC decrease with LPS (significant) and LPS + nanoparticle groups. vWF increase with LPS (significant) and LPS + 14 nm (significant). |
| Reference: Inoue et al. (2004, 087984) Species: Mouse Gender: Male Strain: ICR Age: 6wks Weight: 29-33g | DEPs [4JB-1 type light-duty, four-cylinder, 2.74 litre Isuzu diesel engine (Isuzu Automobile Co., Tokyo Japan)] Washed DEP and DEP-OC - extracted with dichloromethane Particle Size: NR | Route: IT instillation Dose/Concentration: Vehicle group: PBS Washed DEP group: 4mg/kg of DEP DEP-OC group: 4mg/kg of DEP-OC LPS group: 2.5mg/kg of LPS Washed DEP + LPS group: combined administration of washed DEP + LPS DEP-OC + LPS group: combined administration of DEP-OC + LPS Time to Analysis: 4h | COX-1 mRNA: Slightly elevated in both washed DEP and DEP-OC groups, but slightly decreased in other groups compared to vehicle group. COX-2 mRNA: Slightly increased with DEP-OC, increased with LPS, washed DEP + LPS and DEP-OC + LPS groups compared to vehicle. COX-2 in the DEP-OC + LPS decreased when compared to the LPS only group. Pulmonary Oedema: Washed DEP + LPS group showed a synergistic enhancement of pulmonary oedema and local expression of proinflammatory chemokines (MCP-1, MIP-1α, KC, IL-1B). |
| Reference: Inoue et al. (2006, 190142) Species: Mouse Gender: Male Strain: ICR Age: 6-7wks Weight: 29-33g | Carbon black (14 nm PrinteX 90; 56nm PrinteX 25; Degussa, Dusseldorf, Germany) Particle Size: 14 nm - 300 m ² /g 56nm - 45 m ² /g | Route: IT instillation Dose/Concentration: Vehicle group: PBS Ovalbumin (OVA) group: 1mg OVA Nanoparticle groups: 50mg carbon black nanoparticles (14nm or 56nm) OVA + nanoparticle group: combined administration of nanoparticles and OVA Time to Analysis: Vehicle group - weekly for 6wks OVA group - biweekly for 6wks Nanoparticle groups - weekly for 6wks OVA + Nanoparticle group (same protocol as OVA and Nanoparticle) studied 24h after last administration | Nanoparticles: Exposure to carbon nanoparticles resulted in the lung expression of TARC, GM-CSF and MIP-1α. The levels were higher in the 14nm group compared to the 56nm group. OVA: In the presence of OVA, nanoparticles enhanced levels of TARC, GM-CSF, MIP-1α, IL-2 and IL-10, with the effects seen more prominently in the 14 nm particles + OVA group. |

| Reference: Jang et al. (2005, 155313) Species: Mouse Gender: Female Strains: BALB/c Age: 5-6wks | DEP -generated from 4JB1 type, light duty, four-cylinder diesel engine (Isuzu Automobile, Co,Tokyo Japan) Ozone - (generated with Sander Model 50 ozonizers,Sander, Eltze Germany) OVA Particle Size: NR | Route: Whole-body Exposure Chamber Dose/Concentration: DEP: 2,000 $\mu\text{g}/\mu\text{L}$ (sic) Ozone: 2 ppm (ave 1.98 \pm 0.08 ppm) OVA sensitization: 10 mg OVA challenge: Time to Analysis: OVA sensitization DEP, Ozone and OVA Challenge on d21- 23 Exposed to ozone for 3h and DEP for 1h AH and BAL measured 1d after last challenge | Airway responsiveness: OVA + ozone + DEP exposure group had significantly higher methacholine-induce Ptnh than sham group or OVA group. Total cells, proportion of eosinophils and neutrophils: the OVA + ozone + DEP group was significantly higher than than OVA group and OVA + Ozone group IL-4: OVA + ozone, OVA + DEP and OVA + ozone + DEP IL-4 level increased compare to OVA group. IFN-α: levels significantly decreased in OVA + DEP and OVA + ozone + DEP compared to OVA + ozone |
| Reference: Jaspers et al. (2005, 088115) Species: Human Cell Lines: A549 cells, primary human bronchial and nasal epithelial cells | DE _{as} : aqueous-trapped solution of DE (emissions from Caterpillar diesel engine, model 3304) Influenza: A/Bangkok/1/79 (H3N2 serotype) Particle Size: NR | Route: Cell Culture. DE _{as} and virus added to apical side of cells Dose/Concentration: Influenza: 3 x 10 ⁵ cells infected with 320 hemagglutination units (HAU) DE _{as} : For A549 cells: 6.25, 12.5, 25 $\mu\text{g}/\text{cm}^2$. For bronchial and nasal cells: 22 or 44 $\mu\text{g}/\text{cm}^2$. Time to Analysis: 2h incubation with DE _{as} then virus added. HA RNA levels analyzed at 0, 15, 30, 60 or 120min post infection. IFN and MxA responses: analyzed 24h post infection. Fluorescence: some cells treated with GSH-ET 30 min before DE _{as} exposure. Measured 2 h post-influenza infection. | A549 cells increased susceptibility: DE _{as} enhances HA RNA levels in A549 cells in a dose-dependent manner. 25 mg/cm ² significantly enhanced levels in A549 cells compared to the influenza-infected controls. Viral protein levels were increased in A549 cells. Exposure to DE _{as} increased the number of influenza-infected epithelial cells in A549 cells. Human nasal and bronchial cells susceptibility: Exposure to DE _{as} increased HA RNA levels in the nasal and bronchial cells. Statistically significant at 22mg/cm ² for nasal cells and approaching significance at 44 mg/cm ² for bronchial cells. Exposure of both types to 44 mg/cm ² enhanced viral protein levels. Influenza induced IFN response in A549: Exposure to DE _{as} does not suppress but enhances IFNB mRNA levels. Treatment enhanced influenza-induced nuclear levels of both phospho-STAT-1 and ISFG3g. ISRE-promoter activity was enhanced, but not significantly. Treatment enhanced myxovirus resistance protein (MxA) mRNA levels. This data suggest that DE _{as} exposure enhances influenza virus replication without suppressing production of IFNB or IFNB-inducible genes. Influenza induced IFN response in human nasal and bronchial cells: Exposure to DE _{as} increased IFNB and MxA levels. Oxidative stress in A549: DE _{as} exposure dose-dependently increases oxidative stress in A549 cells within 2-h post-exposure. Add the antioxidant GSH-ET and it reverses the effect. Pretreatment with GSH-ET A549 cells reversed the effects of DE _{as} on the number of influenza-infected cells, and reduced HA RNA levels. Oxidative stress in Human bronchial cells: The results were the same as A549 cells pretreated with GSH-ET. Or Pretreatment with GSH-ET also reversed effects of DE _{as} on HA RNA levels. |

| Reference: Kaan and Hegele (2003, 095753) Species: Guinea pig Gender: Female Strain: Cam Hartley Age: 22-29d Weight: 250-300g Cell Types Alveolar macrophages (AM) obtained by bronchoalveolar lavage | PM ₁₀ - EHC-93 obtained (Environmental Health Canada, Ottawa, ON, Canada) RSV - Human RSV (long strain/lot18D) (American Tissue Culture Collection, Bethesda, MD) Particle Size: PM ₁₀ (0.35µm MMAD) | Route: Cell Culture Dose/Concentration: PM ₁₀ : 500 µl/well (100 µg/ml MEM) RSV exposure:: 1 ml/well (6x10 ⁶ pfu/ml MEM) Groups: PM ₁₀ + RSV RSV + PM ₁₀ RSV only PM ₁₀ only negative control Time to Analysis: PM ₁₀ - 60min RSV - 90min Parameters measured 24h post treatment | Interaction on phagocytic ability of AM: Not affected by sequential exposure to RSV and PM ₁₀ . More than 95% of AM exposed to PM ₁₀ engulfed PM. AM exposed to PM ₁₀ showed significant increase in mean side scatter in comparison to negative control and RSV-infected AM. No significant difference between AM exposed only to PM ₁₀ and AM exposed to both agents. No significant side mean side scatter difference between AM exposed to PM only and to both agents. Interaction on RSV Immunopositivity: PM ₁₀ exposure inhibits. All RSV-treated groups showed significantly greater proportion of RSV-immunopositive cells compared with negative control. PM ₁₀ + RSV showed significantly smaller proportion of RSV-immunopositive cells compared with RSV group. RSV + PM ₁₀ group similar to RSV group. Proportion of RSV-immunopositive AM was influenced by the sequence of exposure to RSV and PM ₁₀ . Interaction on RSV Replication: PM exposure suppressed RSV replication. AM exposed to both agents produced 3 to 9 fold less RSV progeny compared with RSV alone group. Quantity of RSV progeny was not significantly affected by the sequence of exposure RSV and PM ₁₀ . Negative control and PM ₁₀ only did not propagate progeny. Interaction of RSV Yield: RSV alone group produced the highest RSV yield, those exposed to both agents, independent of sequence, showed a 5-fold decrease. Cytokine production: RSV infection stimulated all three cytokines measure (IL-6, IL-8 and TNF-α) compared to negative control. IL-6: PM ₁₀ significantly reduced RSV-induced IL-6 production. IL-6 was affected by the sequence of exposure to PM ₁₀ and RSV (PM ₁₀ + RSV vs. RSV + PM ₁₀ , p < 3x10 ⁻⁶). IL-8: PM ₁₀ significantly decreases RSV-induced IL-8 production and baseline. No effect on sequence of exposure. TNF-α: production was increased when exposed to RSV, PM ₁₀ or a combination of both agents. No differences among treatments. |

Washed particles of ROFA at doses 2.5 to 10 mg/cm ² significantly increased inducible TAP expression. Soluble Metals in BTE: V ₂ O ₅ inhibition of LPS and IL-1B induced TAP gene expression increases with exposure time and dose. NiSO ₄ exhibits non-significant dose dependent suppression of inducible TAP gene expression. Fe ₂ (SO ₄) ₃ , TiO ₂ and SiO ₂ were found to have no effect. A549: Results with ROFA and V ₂ O ₅ in BTE were replicated using the A549 cell line and IL-1B to induce hBD2 gene expression. Cellular Viability: Was not significantly affected in ROFA doses below 20 μg/cm ² and V ₂ O ₅ /VOSO ₄ doses below 2.5 μg/cm ² . |
| Reference: Koike and Kobayashi (2005, 088303) Species: Rat Gender: Male Strains: Wistar Age: 8-10 wks Weight: 280-350g Cell Types AM - alveolar macrophages PBM - peripheral blood monocytes T-cells: antigen sensitized | Whole DEP: Diesel Exhaust Particles collected in the dilution tunnel of a diesel inhalation facility. (Ratio of organic extract to residual particles in the whole DEP was 3: 1.) Organic extract of DEP Residual particles of DEP OVA: Ovalbumin (Sigma, St. Louis, MO) Particle Size: NR | Route: Cell Culture Dose/Concentration: Whole DEP: 10, 30, 100 μg/mL Organic extract of DEP: 7.5, 22.5, 75 μg/mL Residual particles: 2.5, 7.5, 25 μg/mL Time to Analysis: 24h post exposure | Ia antigen and costimulatory molecules: Most control AM did not express these molecules. Whole DEP did not cause any increase in expression level. 20% of control PBM expressed Ia and 10% B7; expression of these molecules was significantly increased by whole DEP. Organic extract significantly increased the expression of Ia and B7 molecules on PBM similar to whole DEP. Residuals caused no effect. PBM exposure to 100/75/25 μg/mL of DEP/organic extract/residual particles: Results showed that the DEP-increased expression of Ia and B7 in PBM by DEP was caused by the organic extract fraction. Organic extract-induced expression of Ia antigen in PBM was reduced by treatment with NAC. AP activity of PBM: After exposure to organic extract, T cell proliferation was significantly increased by the addition of control PBM in a cell number-dependent manner. AP activity of PBM was increased over control by exposure to 3 mg/mL organic extract, although higher concentrations suppressed the activity of PBM. Cytokine production: Organic extract treatment of PBM decrease IFNα production from T-cells stimulated by PBM. No significant effect on IL-4 observed. HO-1 protein level: levels in PBM was significantly increased by exposure to whole DEP or organic extract. Levels induced by organic extract was diminished by NAC treatment. |

| Reference: Last et al. (2004, 097334) Species: Mouse Gender: NR Strains: BALB/c Age: 6wks Weight: 16-20 g | PM - aerosol of soot and iron oxide OVA (ovalbumin, grade V, 98% pure,) Particle Size: PM _{0.1} - PM _{2.5} | Route: PM -Exposure Chamber OVA - Intraperitoneal Injections; Aerosol Exposure Dose/Concentration: PM – 235 – 256 $\mu\text{g}/\text{m}^3$ OVA - 10 $\mu\text{g}/0.1\text{mL}$ injection OVA aerosol – 10mL of 10mg/mL (1%) solution Time to Analysis: PM: 4h/d, 3 d/wk OVA: 2 ip injections days 1 and 15. Aerosol on day 28 after first ip; 60 min 3x/wk | 2wk PM exposure/4wk OVA aerosol treatment: The OVA alone group had significantly more airway collagen than the PM alone group. Histology showed significantly more collagen in the treatment than the air alone group. There was a significantly greater amount of goblet cells than the OVA alone group. 4wk OVA aerosol/2wk PM treatment: The treatment had significantly more goblet cells than the PM alone group. 6wk concurrent PM and OVA treatment: Significantly more cells were observed in the OVA alone group over the treatment. The treatment had significantly more lymphocytes and significantly less macrophages than groups exposed to PM before or after OVA. Histology showed significantly more collagen in the treatment than the air or PM alone groups. The treatment had significantly more goblet cells than the OVA alone group. |
| Reference: Li et al. (2007, 093156) Species: Mouse Gender: Female Strain: BALB/c, C57BL/6 Age: 9wks Weight: NR | DEP (2369-cc diesel engine manufactured by Isuzu Motor, operated at 1050 rpm, 80% load, commercial light oil) Particle Size: NR | Route: Exposure Chamber Dose/Concentration: DEP: $103.1 \pm 9.2 \mu\text{g}/\text{m}^3$, CO: $3.5 \pm 0.1\text{ppm}$, NO ₂ : $2.2 \pm 0.3\text{ppm}$, SO ₂ : $< 0.01\text{ppm}$ Time to Analysis: Protocol 1: Exposed 7h/d, 5d/wk. Sacrificed at day 0, week 1, 4, 8. Protocol 2: DE alone or DE+NAC 7h/d, 1-5d. | Airway hyperresponsiveness: Penh values increased in BALB/c mice compared to the control at day 0, but no significant changes occurred after this time. Penh values increased in C57BL/6 mice at 1wk compared to the control but returned to control levels at 8wks. BALF: Compared to the other strain, the total number of cells and macrophages increased significantly at 1wk in C57BL/6 mice and at 8wks in BALB/c mice. Neutrophils, lymphocytes, MCP-1, IL-12, IL-10, IL-4, IL-13 increased significantly for both strains. No eosinophils were found. IL-1B and IFN- α increased significantly in BALB/c mice compared to C57BL/6 mice. HO-1 mRNA and protein: HO-1 mRNA was more marked in BALB/c mice at 1wk and C57BL/6 mice at 4 and 8wks. HO-1 protein percentage changes from the control were greater in BALB/c mice at 1wk and C57BL/6 mice at 8wks. NAC: NAC inhibited the increased Penh values, total number of cells and macrophages in C57BL/6 mice at 1wk and neutrophils and lymphocytes in both strains. |
| Reference: Li et al. (2009, 190424) Species: Mouse Gender: Female Strain: BALB/c Age: 6-8wks Weight: NR | CAPs (downtown Los Angeles, CA from major freeway, traffic mainly passenger cars and diesel trucks; Jan. 2007 or Sept. 2006) Ultrafine carbon black (UFCB; used as control) Particle Size: Diameter: Fine- $< 2.5 \mu\text{m}$, UF- $< 0.15 \mu\text{m}$ | Route: Intranasal Instillation Dose/Concentration: 0.5 μg PM in 50 μL suspension Time to Analysis: Day 1 exposed to PM or saline. Day 2 exposed to PM+OVA or OVA or saline alone. Repeated on days 4, 7, 9. Different experiment: NAC ip injected 4h pre-instillation on days 1, 2, 4, 7, 9. All animals rested and OVA aerosol challenged 30min on days 21, 22. Sacrificed day 23. | UFP alone had no effect on the lung. UFP+OVA significantly increased eosinophils, and OVA-specific IgG1 and IgE. The induction of eosinophils and IgG1 were inhibited by NAC. Generally, UFP+OVA mice had greater signs of inflammation than the other groups as determined by pulmonary histopathology and airway morphometry. UFP had a greater PAH content than fine particles. UFP significantly increased IL-5, IL-13, TNF- α , IL-6, KC, MCP-1, and MIP-1 α . |
| Reference: Li et al. (2009, 190424) Species: Mouse Cell Line: Macrophage RAW 264.7 | CAPs (downtown Los Angeles, CA from major freeway, traffic mainly passenger cars and diesel trucks; Jan. 2007 or Sept. 2006) Ultrafine carbon black (UFCB; used as control) Particle Size: Diameter: Fine- $< 2.5 \mu\text{m}$, UF- $< 0.15 \mu\text{m}$ | Route: Cell Culture Dose/Concentration: 1, 5, 8.3, 10 $\mu\text{g}/\text{mL}$ Time to Analysis: Particle suspensions reconstituted with Dulbecco's Modified Eagle's Medium powder. Further replenished with 10% fetal calf serum and 1:200 dilution of penicillin/streptomycin/amphotericin B. Incubated 16h. 100 μg of lysate protein for HO-1 immunoblotting. | UFP induced greater HO-1 expression than fine particles. The higher PAH content of UFP correlated with HO-1 expression. |

| Reference: Liu et al. (2008, 156709) Species: Mouse Gender: Female Strain: BALB/c Age: 11wks Weight: NR | DEP (5500-watt single-cylinder diesel engine generator (Yanmar, Model YDG 5500E), 406 cc displacement air-cooled engine, Number 2 Diesel Certification Fuel, 40 weight motor oil) Particle Size: MMAD: ~ 0.1 μ m | Route: Intranasal Exposure Dose/Concentration: Average particle concentration: 1.28mg/m ³ Time to Analysis: Four groups: saline + air control, saline + DEP, <i>A. fumigatus</i> + air, <i>A. fumigatus</i> + DEP. <i>A. fumigatus</i> exposure every 4d for 6 doses. DEP exposure 5h/d for 3wks concurrent with <i>A. fumigatus</i> exposure. | <i>A. fumigatus</i> + DEP increased IgE, the mean BAL eosinophil percentage, goblet cell hyperplasia, and eosinophilic and mononuclear cell inflammatory infiltrate around the airways and blood vessels compared to the <i>A. fumigatus</i> or DEP treatments. <i>A. fumigatus</i> + DEP also caused methylation at the IFN- γ promoter sites CpG ⁻⁵³ , CpG ⁻⁴⁵ , and CpG ⁻²⁰⁵ . |
| Reference: Liu et al. (2007, 093093) Species: Mouse Gender: Female Strain: BALB/c Age: 11wks | DEP: 5500-watt single-cylinder diesel engine. Particle Size: NR | Route: Inhalation Exposure Dose/Concentration: Average particle concentration 1.28 mg/m ³ . Time to Analysis: 1. Aerosol vehicle (saline) + air 2. Aerosol vehicle (saline) + DEP 3. <i>A. fumigatus</i> + air 4. <i>A. fumigatus</i> + DEP <i>A. fumigatus</i> : 62.5 μ g aerosolized protein extract in 50 μ L PBS; 6 total doses, every 4d. DEP exposure 5h/d 3wks concurrent with <i>A. fumigatus</i> . | IgE Production: IgE production increased with the <i>A. fumigatus</i> treatment and increased further with the <i>A. fumigatus</i> and DEP treatment. Histopathology: <i>A. fumigatus</i> with DEP caused an increase in goblet cell hyperplasia and eosinophil and mononuclear cell infiltrate around the airways and blood vessels as compared to the control and DEP treatments. Gene Methylation: Greater methylation at the CpG ⁻⁵³ site of the IFN- γ promoter occurred under the <i>A. fumigatus</i> + DEP treatment compared to the <i>A. fumigatus</i> or DEP treatments. The DEP treatment did not induce methylation. Methylation correlated with increased IgE and hypomethylation with decreased IgE. Hypomethylation occurred in the IL-4 promoter under the <i>A. fumigatus</i> + DEP treatment. |
| Reference: Lundborg et al. (2007, 096040) Species: Rat Gender: Male Strains: Sprague-Dawley Age: NR Weight: 300-400g | Carbon-Black Particles (93% C) Toluene- DEPs (97% C) 10-fold Cr, Mn, Ni; 50-100 fold Al, Cd, Cu, Fe, Mg, Pb, Zn more in DEP aggregates Particle Size: Carbon aggregates- mean diameter = 0.17 \pm 0.08 μ m Diesel Particles- mean diameter: 0.69 \pm 0.46 μ m mean size primary particles: 0.044 \pm 0.01 μ m | Route: Cell Culture {Citation} Dose/Concentration: 2 X 10 ⁶ AM A 2mL suspension was prepared with 20 μ g/mL of carbon or diesel particles added. surface area: 159 \pm 4m ² /g Time to Analysis: 6 different experiments. AM pre-exposed to carbon or washed DEP. Loaded with particles. Incubated with <i>S. pneumoniae</i> , ATCC strain or clinical isolates. | Effect of time on survival of <i>S. pneumoniae</i> when incubated with carbon loaded AM: Loading AM with carbon significantly increased the bacterial survival. Bacteria opsonization decreased bacterial survival. Effect of carbon load in AM on survival of <i>S. pneumoniae</i>: Bacterial survival increased in a dose-dependent manner as the carbon particle load of AM increased. Survival of <i>S. pneumoniae</i> after incubation with carbon or washed diesel loaded AM: Bacterial survival increased in carbon loaded AM compared to the control. No difference existed with the washed diesel particles. Survival of the ATCC strain and clinical isolates of <i>S. pneumoniae</i> when incubated with carbon loaded AM or control AM: Carbon significantly increased the CFU of opsonized and unopsonized bacteria for the ATCC strain and clinical isolates. Ability of carbon or washed diesel loaded AM, incubated with the ATCC strain of <i>S. pneumoniae</i>, to induce LPO of lung surfactant: A 97% increase in the surfactant LPO occurred after incubation with washed diesel loaded AM compared to control AM. The effect of washed diesel particles was significantly greater than that of carbon particles. LPO by carbon loaded AM incubated with the ATCC strain or clinical isolates in the presence or absence of surfactant: LPO induced by AM increased when incubated with carbon loaded AM compared to control AM. |

| Reference: Matsumoto et al. (2006, 189213) Species: Mouse Gender: Female Strains: BALB/c Age: 6wks Weight: 15-20g | DE DE collected from a 2369 cm ³ diesel engine operated at 1050 rpm and 80% load with commercial light oil. Engine exhaust passed through a particulate air filter and charcoal filter. Diluted DE introduced into the exposure chamber. Composition of the DE: 3.5 ± 0.1ppm CO, 2.2 ± 0.3ppm NO ₂ , < 0.01ppm SO ₂ and 103.1 ± 9.2 μg/m ³ DEP. Particle Size: NR | Route: Whole-body exposure chambers after prior sensitization with OVA through ip injection Dose/Concentration: 100 μg/m ³ DE Time to Analysis: Mice were initially sensitized w/ OVA (20ug absorbed to 2 mg alum diluted with 0.5 mL saline) via ip injection on day 0, 6 and 7. Two weeks later the mice were challenged with OVA (0.1mg in 0.1mL saline) intranasally on day 21. DE for 1d or 1,2, 3, 4 or 8wks (at 7h/d for 5d/wk). | Airway Hyper-Responsiveness: Airway Reactivity (evaluated by an increase in PenH)- Exposure to DE significantly increased airway reactivity to methacholine after 1 week in both 24 and 48 mg/mL Mch and after 4 weeks in the 48 mg/mL. Airway Sensitivity (evaluated by PC200)- DE exposure caused an increase in airway sensitivity after 1 week of exposure, 4 weeks and 8 weeks of exposure did not result in a significant increase. BAL Cell Counts: The total cell count was increased after 1 week of DE exposure. This increase was mostly due to an increase in eosinophils. After 1 week the total cell count dropped drastically even after continuous exposure to DE. DE did not effect the number of CD3, CD4, CD8 or NK1 cells at any point in time. Cytokine/Chemokine mRNA Levels: DE exposure on day 1 caused an increase in mRNA levels of IL-4, IL-5 and IL-13 when compared to the control mice but longer periods of DE exposure failed to cause an increase. Protein levels of IL-4 were significantly elevated at compared to control at day 1, but did not persist with time. mRNA levels of MDC were increased at 1 week of exposure (compared to control) but also decreased at time periods after. mRNA levels of RANTES were increased at 2 and 3 weeks after exposure and remained elevated at 4 weeks but not significantly. The level of RANTES protein increased as the weeks went along, but increased significantly only at 8 weeks. Lung Histopathology: OVA sensitization caused an increase peribronchial and perivascular infiltration of inflammatory cells which peaked at 1 week after exposure and decreased afterward. DE exposure did not cause/show any additional signs of inflammation. |
| Reference: Morishita et al. (2004, 087979) Species: Rat Gender: Male Strain: Brown-Norway Age: 10-12wks | Concentrated Air Particles (CAPs) CAPs were generated from ambient air in an urban Detroit community. The sampling site was chosen because it has a high percentage of pediatric asthma and is located near a lot of industry. Particle Size: 0.1-2.5 μm | Route: Whole-body Inhalation Chambers Dose/Concentration: Air chamber received CAPs at a flow rate of 50 L/min and at a pressure of 0.94-0.95 atm. July 676 μg/m ³ September 313 μg/m ³ Time to Analysis: First rats were sensitized (days 1-3) and challenged (days 14-16) with saline (control) or ovalbumin by intranasal instillation (5% in saline, 150 μL/nasal passage). 4 days after the last intranasal challenge, rats began exposure in the chambers. Exposures were 10 h long. There were two separate exposure periods in July and September. The July exposure was for 4 consecutive days. The September exposure was for 5 consecutive days. | Recovery of Trace Elements in Animal Lung Tissues: July Exposure- Anthropogenic trace elements were below limit of detection in pulmonary tissue of animals exposed to July CAPs. September Exposure- Several elements were recovered from pulmonary tissue during the Sept. exposure. La concentrations were increased in both control/CAPs exposure and in the Ova/CAPs exposure groups. V concentration was increased in Ova/CAPs exposed animals but not in rats exposed to just CAPs. S content was only significant in animals exposed to Ova/CAPs compared to the non-exposed control. Particle Characterization: July PM had an average mass concentration twice as high as the September mass concentration. S concentration was four-folds higher in July PM. In the September PM- the concentration of La was 12.5 fold higher than in July PM, V was 2.7 fold higher than in July PM and Mn was 1.5 fold higher than in July PM. BALF Analysis: Eosinophil concentration was not significantly different when comparing rats exposed to CAPs only in either July or September (this was explained by the elapsed time between exposure and BALF collection). However OVA and CAP exposure in the September group led to elevated eosinophil levels. Similarly, the protein content was only significantly increased in the September OVA/CAP exposed rats, compared to the control group. |

| Reference: Nygaard et al. (2004, 058558) Species: Mouse Gender: Female Strain: BALB/c Age: 6-7wks Weight: NR | CB (carbon black/DEP) Polystyrene Particles (PSP) Particle Size: PSP diameter: 0.0588, 0.202, 1.053, 4.64 or 11.14 μm | Route: Single subcutaneous injection into footpad Dose/Concentration: 10 μg OVA + 40 μg (low dose) or 200 μg (high dose) of particles Time to Analysis: Mice killed 5d after OVA injection; PLN excised | OVA Specific IgE and Ig2a: OVA with CB, DEP or PSP of diameters 0.0588 and 0.202 μm increased IgE compared to OVA alone, as well as the 1.053, 4.64 and 11.14 μm PSP. OVA with 0.0588 μm PSP or CB significantly increased IgG2a compared to OVA alone. Primary Cellular Response: All OVA and PSP groups (except the low dose of 11.14 μm PSP) had more total lymph node cell numbers than the OVA alone group. The low and high dose groups of 0.202 μm PSP had the greatest amount of cell proliferation and lymphoblasts. The OVA and 0.202 PSP treatment produced the greatest amounts of B lymphocytes, IL-4, IL-10 and IFN- α . IL-2 in the PLN cells was significantly lower in both dosage groups of OVA and 0.202 PSP than the OVA control. Particle mass, size, number and surface area: Total particle surface area explained 64% of the variance in the IgE levels. 60-80% variance of the PLN cellular parameters (except CD23) were explained by total particle surface area, number and diameter. |
| Reference: Reed et al. (2008, 156903) Species: Mouse Gender: Male, Female (only BALB/c) Strain: C57BL/6, A/J, BALB/c Age: NR Weight: NR | GEE (two 1996 General Motors 4.3-L V-6 engines; regular, unleaded, non-oxygenated, non-reformulated gasoline blended to US average consumption for summer 2001 and winter 2001-2002-Chevron-Phillips) Particle Size: MMAD: 150nm | Route: Inhalation Exposure Chamber Dose/Concentration: PM: Low- $6.6 \pm 3.7 \mu\text{g}/\text{m}^3$, Medium- $30.3 \pm 11.8 \mu\text{g}/\text{m}^3$, High- $59.1 \pm 28.3 \mu\text{g}/\text{m}^3$ Time to Analysis: A/J- 2wk quarantine period in chamber. Exposed 6h/d, 7d/wk, 3d-6m. C57BL/6- 1wk exposure. Instillation of <i>P. aeruginosa</i> . Killed 18h postinstillation. BALB/c- Conditioned to exposure chambers and mated. Pregnant females exposed GD 1 and throughout gestation. Offspring exposures continued until 4wks-old. Half of offspring sensitized to OVA. Tested for airway reactivity by methacholine challenge 48h postinstillation and euthanized. | The kidney weight of female A/J mice decreased at 6m and was strongly related to PM by the removal of emission PM. PM-containing macrophages increased by 6m. Hypomethylation occurred in females at 1wk. The clearance of <i>P. aeruginosa</i> was unaffected by exposure. Serum total IgE significantly and dose-dependently increased. OVA-specific IgE and IgG1 gave slight exposure-related evidence but were not significant. |
| Reference: Reed et al. (2008, 156903) Species: Rat Gender: Male, Female Strain: CDF (F344)/CrIBR, SHR Age: NR Weight: NR | GEE (two 1996 General Motors 4.3-L V-6 engines; regular, unleaded, non-oxygenated, non-reformulated Chevron-Phillips gasoline, U.S. average consumption for summer 2001 and winter 2001-2002) Particle Size: MMAD: 150nm | Route: Inhalation Exposure Chamber Dose/Concentration: PM: Low- $6.6 \pm 3.7 \mu\text{g}/\text{m}^3$, Medium- $30.3 \pm 11.8 \mu\text{g}/\text{m}^3$, High- $59.1 \pm 28.3 \mu\text{g}/\text{m}^3$ Time to Analysis: 2wk quarantine period in chamber. Exposed 6h/d, 7d/wk, 3d-6m. SHR- surgery to implant telemeter in peritoneal cavity. 4wks recovery. ECG data obtained every 15min beginning 3d preexposure, 7d exposure, 4d postexposure. | Organ Weight: At 6m exposure, the heart weights of male and female rats increased and male rats' seminal vesicle weight decreased. Histopathology: PM-containing macrophages increased by 6m. Serum Chemistry: Serum alanine aminotransferase, aspartate aminotransferase, and phosphorus decreased in medium and high-exposure females. Hematology, Clotting Factors: Hematocrit, red blood cell count, and hemoglobin dose-dependently increased for both genders at both time points. Plasma fibrinogen increased at 1wk in males. Lung DNA Damage: Hypermethylation occurred in medium- and high-exposure male rats at 6m. BAL: For both genders in the high-exposure group, LDH and MIP-2 significantly increased at 6m. ROS decreased at 1wk and 6m. Generally, the production of hydrogen peroxide and superoxide decreased in the high-exposure group and medium- and high-exposure groups, respectively. CV effects in SHR: Lipid peroxides were significantly increased in males in the high exposure group. TAT complexes decreased in females in the high exposure group. Removal of Emission PM: The removal of emission PM strongly linked PM to increased seminal vesicle weight, red blood cell counts, LDH, lipid peroxides, and methylation. |

| Reference: Roberts et al. (2007, 097623) Species: Rat Gender: Male Strain: Sprague-Dawley Age: 10wks Weight: 250-300g | R-Total = ROFA (Residual oily fish ash) Sample R-Soluble = Soluble fraction of ROFA R-Chelex = R-Soluble + Chelex (insoluble resin) Particle Size: Mean diameter- 2.2 μm | Route: IT Instillation Dose/Concentration: 10mg/kg of body weight (2.5-3mg) Time to Analysis: Pre-exposure to ROFA samples on Day 0. Inoculation with 5×10^4 L. Monocytogenes or saline on day 3. Sacrifice on days 6, 8, 10. | Uninfected groups: Compared to the controls, the R-total and R-soluble groups had increased LDH, PMNs, lymphocytes and AMs. The R-total group had a slight, but significant increase in IL-6 and the R-soluble group had a decrease in IL-2. Infected groups: The R-soluble group had increased levels of LDH (which also increased for the R-total group), albumin, BAL cells, NK cells, PMA-stimulated and zymosan-stimulated CL compared to all other groups at various time points. NO _x was significantly elevated in the R-soluble group at early time points, but in later time points R-soluble and R-total AMs produced less NO _x than the controls. IL-10 and IL-6 increased in the R-soluble group, while IL-12, IL-4 and IL-2 decreased. IL-12 also decreased in the R-total group. |
| Reference: Saxena et al. (2003, 054395) Species: Mouse Gender: Female Strain: C57B1/6J Age: 18-30wks Weight: NR | DEPs (standard) Particle Size: NR | Route: Intrapulmonary Instillation Dose/Concentration: 100 μg /mouse Time to Analysis: Pre-exposure to 2.5×10^4 bacillus Calmette-Guerin bacteria (BC G) with or without coadministration of DEP. Sacrifice 5wks later. | The BC G + DEP group had four times the BC G lung load than BC G alone. The load was significantly greater in other organs in the BC G + DEP group. Interstitial lymphocytes, T, B and NK cells were increased in the BC G + DEP group over the DEP-alone group. DEP caused no release of NO by AMs, but inhibited the release of NO in response to IFN- α . Except for CD8 cells, no increase in IFN- α was seen in the BC G + DEP group. |
| Reference: Schneider et al. (2005, 088368) Species: Mouse Strain: BALB/c Cell Line: RAW 264.7 macrophage cells | SRM 1648 (greater than 63% inorganic carbon; 4-7% organic carbon; Si, S, Fe, Al, K greater than 1% by weight; Mg, Pb, Na, Zn, Cl, Ti, Cu, As, Cr, Ba, Br, Mn less than 1%) Titanium dioxide Particle Size: TiO ₂ = 0.3 μm average, 1.0 μm max SRM 1648 = 0.4 μm mean diameter | Route: Cell Culture (625,000 cells/cm ² in 96 well plate) Dose/Concentration: 62.5 $\mu\text{g}/\text{cm}^2$ Time to Analysis: Particulate introduction at 0, 7.8, 15.6, 31.2, and 62.5 $\mu\text{g}/\text{cm}^2$. Measurements made at 1, 3, 6, and 12h after particulate introduction. | No significant toxicity was exhibited by SRM 1648. The rate of dye oxidation was significantly higher in SRM 1648-exposed cells. SRM 1648 significantly increased reduced glutathione compared to the control at the 12-h time point. SRM 1648 increased GSH and concurrently caused significant PGE ₂ production compared to the no ester control at the 6-h and 12-h time points. |
| Reference: Schober et al. (2006, 097321) Species: Human Gender: Male and Female Age: 21-39yrs, treatment group; 23-32yrs, control group Tissue Type: Whole blood samples | PM – organic extracts of airborne sample AERex ^{1d} – urban aerosol 1 day sample (total air volume - 1270m ³) AERex ^{5d} – urban aerosol 5 day sample (total air volume - 6230m ³) rBet v 1 (birch pollen allergen 1a, Biomay, Vienna, Austria) Particle Size: NR | Route: Cell Culture Dose/Concentration: 100 μL heparinized whole blood Time to Analysis: Blood stimulated with PBS/IL-3 for 10min. Incubated with rBet v 1 alone or with AERex for 20min. Ice bath 5min. Incubated with antibody reagent 20min. | Nine organic compound classes were identified in AERex ^{1d} and AERex ^{5d} , with AERex ^{1d} having 20 times more PAHs. Basophil activation increased in all treatment groups up to 90%, with AERex ^{1d} being the most pronounced. 5-50 fold lower concentrations of AERex ^{1d} were needed to achieve the maximal effect on basophil activation. AERex-induced enhancement of CD63 upregulation of rBet v 1 in sensitized basophils occurred in a dose-dependent manner. The AERex-alone treatment did not affect CD63 expression. |

(2005, 111553) Species: Mouse Gender: Male Strains: BALB/c Age: 8 wks Weight: NR | CB = carbon black particles (Degussa, Germany) CB14: C: 96.79% H: 0.19% N: 0.13% S: 0.11% Ash: 0.05% Others including O: 2.74% CB95: C: 97.98% H: 0.15% N: 0.28% S: 0.46% Others including O: 1.14% Particle Size: CB14 = 14nm primary particle size (pps) CB95 = 95nm (pps) | Route: IT instillation Dose/Concentration: 25, 125, or 625 μ g in 1 mL saline solution Time to Analysis: CB14 or CB95 instillation 1/wk for 4wks Sacrifice 24 or 4h after last instillation | BAL cells: In CB14, the total number of BAL cells increased significantly and dose-dependently. In CB95, only the 625 μ g dose showed a significant increase. Cytokine and chemokine: For CB14 and CB95, 125 or 625 μ g showed a significant IL-1B increase in a dose-dependent manner. For CB14, only the 625 μ g dose showed a significant IL-6 increase. No difference was observed in the CB95 group. For CB14, only larger doses showed a significant TNF α increase. For CB95, no significant differences were observed. In BAL fluid: CCL-2 production was significantly increased for the 625 μ g dose in both the CB14 and CB95 groups. CCL-3 production was significantly increased for the larger doses in both the CB14 and CB95 groups. Splenic Lymphocytes: No significant differences were detected among the CB14 dosages, except for CD8 ⁺ . No significant differences were observed among the various groups for CB95. Deposition in lymph nodes: For all dosages, greater deposition of CB14 than CB95 was observed. Chemokine mRNA expression in lungs and lymph nodes: At 125 μ g, significant increases of CLL-3 mRNA expression was observed for CB14; for CB95, no differences were detected. |

| Reference: Sigaud et al. (2007, 096100) Species: Mouse Gender: Male Strains: BALB/c Age: 8-10wks Weight: NR | CAPs: Concentrated Ambient Particles (Collected from ambient Boston air on Teflon filters.) TiO ₂ IFN α <i>S. pneumoniae</i> (ATCC 6303, American Type Culture Collection, Manassas, VA) Particle Size: CAPs: < 2.5 μ m | Route: IFN α priming: aerosol Particle exposure and infection: Intranasal Instillation Dose/Concentration: CAPs or TiO ₂ : 50 μ g/50 μ L PBS <i>S. pneumoniae</i> : 10 ⁵ CFU/25 μ L saline Time to Analysis: Primed for 15min One time particle exposure 3h post priming with lung RNA analyzed 3, 6, 24h after exposure Sacrificed 24h after exposure OR one time infection Sacrificed 24h infection | Inflammation: Saline-primed and unprimed mice exposed to CAPs produced a significant increase in PMNs in the lung (100% more than mice exposed to TiO ₂ .) Groups primed with IFN α then exposed to CAPs produced a strong inflammatory response, a 2.5 increase in PMNs when compared to the increase caused by PBS+ CAPs exposure. Cytokine Levels: IFN α primed and CAPs exposed groups Inflammation + <i>S. pneumo</i> Infection: Saline-primed and unprimed mice exposed to CAPs produced a significant increase in PMNs in the lung (100% more than mice exposed to TiO ₂ .) Groups primed with IFN γ then exposed to CAPs produced a strong inflammatory response, a 2.5 increase in PMNs when compared to the increase caused by PBS+ CAPs exposure. Cytokine Levels: IFN γ primed and CAPs exposed groups showed a 1.5-fold increase over the control. PMNs: Treatment with CAPs enhanced inflammation, causing a 2-fold increase in PMN numbers as compared to the infected control. IFN γ +CAPs+ <i>S. pneumo</i> produced a 3.5 fold increase compared to the infected control and a 1.6-fold increase compared to PBS+ CAPs+ <i>S.pneumo</i> . Despite increased numbers of PMNs in the IFN γ +CAPs groups, the lungs were unable to clear the <i>S. pneumo</i> infection. Bacterial Load: Control groups showed efficient clearance of bacteria after infection. Unprimed, CAPs-treated, infected groups did not show a decrease in bacterial numbers. IFN γ +CAPs showed a 2.5-fold increase in bacterial numbers. Histopathology: Indicated moderate pneumonia in PBS+CAPs and severe pneumonia in IFN γ +CAPs. The other groups did not indicate areas of pneumonia. Bacterial Uptake AM and PMN Cells: In all the treated groups, the bacterial content in AMs showed a decrease, with a more marked decrease in the IFN γ +CAPs group, but these decreases were not statistically significant. Groups exposed to CAPs showed a statistically significant decrease in bacterial uptake by PMNs. ROS Levels in AM and PMN Cells: Intracellular ROS significantly increased in AM cells in the IFN γ +CAPs group, approximately 50% greater than controls. In PMNs, iROS increased 100% in the IFN γ +CAPs groups as compared to the controls. |

| Reference: Steerenberg et al. (2004, 087474) Species: Rat Gender: Male Strain: Wistar Age: 6-8wks | Ozone (positive control) DEP:SRM1650a (NIST, Gaithersburg, MD) EHC-93: ambient PM (Ottawa, Canada) <i>L. mono: Listeria monocytogenes</i> (strain L242/73 type 4B) Particle Size: Ozone: DEP, EHC-93: NR | Route: Ozone: Whole-body inhalation chamber DEP/EHC-93: intranasal droplet: Dose/Concentration: Ozone: 2mg/m ³ DEP/EHC-93: 50µg (1.0 mg/ml) <i>L. mono:</i> 0.2 or 0.3 ml (5x10 ⁸ PFU/ml) *I have emailed author regarding correct dose Time to Analysis: Ozone 24 h/day for 7 days (-7d to -1dR) DEP/EHC-93: 1/day for 7 days (-7d to -1d) All rats infected on day 0. Sacrificed on days 3, 4, or 5 | Body weight: Growth declined for ozone exposed group while DEP or EHC-93 groups grew progressively. Exposure to <i>L. mono</i> caused all groups to decline in weight. Bacterial Count in the Lung: The number of bacteria in the lung of those rats exposed to ozone was significantly greater than those exposed to saline. No differences in bacteria number were found for rats exposed to saline, EHC-93 or DEP at any time. Bacterial Count in the Spleen: The ozone exposed group exhibited statistically significant increases in bacteria numbers when compared to the saline-treated group. No differences in bacteria number were found for rats exposed to saline, EHC-93 or DEP at any time. Exposure to ozone decreases the defense of the respiratory tract against <i>L. mono</i> infection; however, DEP and EHC-93 did not appear to affect the host defense system in regards to clearing/fighting <i>L. mono</i> . |
| Reference: Steerenberg et al. (2005, 088649) Species: Mouse Gender: Male Strain: BALB/cByJ.ico Age: 6-8wks | PM: collected from Rome, Oslo, Lodz, Amsterdam and De Zilk during the spring, summer and winter. Rome, Oslo, Lodz and Amsterdam represent areas with high population and dominance of traffic. De Zilk, selected as a negative control site, has low traffic emissions and natural allergens. EHC-93: used as a positive control (Gift of Dr. R. Vincent, Ottawa, Canada) OVA: Ovalbumin (Sigma) Particle Size: Coarse PM: 2.5 - 10.0 µm (MMAD); Fine PM: 0.1 - 2.5 µm (MMAD); Ultrafine: < 0.1 µm (MMAD); EHC-93: NR | Route: Intranasal Exposure OVA challenge: aerosol Dose/Concentration: PM: 450 µg PM (at 0, 3, or 9 mg/ml) OVA sensitization: 50 µg (0.4 mg/ml) . OVA challenge: 20 µg (0.4 mg/ml) EHC-93 was administered at 0 - 900 µg to evaluate any dose-response relationship. Time to Analysis: Sensitization and PM exposure on days 0, 14 Challenged on days 35, 38, 41 for 20min/day Sacrificed on day 42 | Effects of Coarse and Fine Particles: Immunoglobulins: 6/13 of the coarse and 9/13 fine PM samples induced an increase in IgE and IgG1 when compared to the control. IgG2a levels were increased in 3/13 of the coarse and 5/13 of the fine PM. Particles from De Zilk induced all three immunoglobulins, except the fine PM did not induce IgG2a. De Zilk was intended as a negative control (see Table 3). Analysis among the sites comparing the subclasses of antibodies indicated a rank as follows: Lodz > Rome ≥ Oslo. Histopathology: 9/13 of the coarse PM samples and 5/13 of the fine PM samples induced an inflammatory response. Bronchoalveolar Cells: Lodz (spring/summer) coarse and fine PM induced a significant increase in eosinophils, neutrophils and monocytes. The coarse and fine PM from Rome (spring) induced an increase in neutrophils and the coarse PM induced an increase in eosinophils. Also both Lodz and Rome from the coarse PM from the spring induced an increase in macrophages. Other PM samples did not have an effect on BAL cell counts. Cytokine Production: None of the samples produced a significant effect on IL-4 levels. IFNα levels were significantly decreased in mice exposed to the fine PM fraction (in 8/13 of the samples) when compared to control. Coarse particle exposure did not appear to affect IFNα levels. TNFα levels were significantly increased (in 2 of the 13 samples) when exposed to coarse PM; fine PM showed similar responses compared to the OVA only group. IL-5 was significantly increased in 4/13 of the coarse and fine PM samples. Analysis of PM Components: Samples from Lodz, Oslo and Rome (all spring) were evaluated and the water-soluble coarse PM fraction showed increased immunoglobulin and pathological responses and the water-insoluble fine PM fraction from Lodz (Spring) showed increased reactivity. Leukocytes and cytokines showed no major differences. |

| Reference: Stevens et al. (2008, 155363) Species: Mouse Gender: Female Strain: BALB/c Age: 10-12 wks Weight: 17-20 g | DE: generated using a 30 kW 4-cylinder Deutz BF4M1008 diesel engine connected to a 22.3 kW Saylor Bell air compressor. The engine was operated on diesel fuel purchased from a service station in Research Triangle Park, NC. The engine was operated at a steady-state, approx. 20% of engine's full load. High composition: O ₂ : 4.3 ± 0.07 ppm NO: 9.2 ± 0.30 ppm NO ₂ : 1.1 ± 0.05 ppm SO ₂ : 0.2 ± 0.10 ppm Low composition: O ₂ , NO, NO ₂ , SO ₂ below detection limits Particle Size: NR | Route: Whole-body Inhalation Chambers (flow rate = 142 L/min) OVA immunization and challenge: intranasal Dose/Concentration: High = 2000 µg/m ³ Low = 500 µg/m ³ Time to Analysis: DE exposure for 4h/d on days 0-4. OVA immunization 40min after DE exposure on days 0-2 Challenged on days 18 and 28. Sacrificed 4h after last exposure of day 4 for gene set analysis or 18, 48, or 96h after the last challenge | IgE Antibody Production: In the absence of OVA, IgE antibodies were not detected. 18, 48 and 96 hours following OVA, mice exposed to low and high doses of DE had an increase in antibodies over time. Mice exposed to high dose had an increase (non-significant) to the OVA exposed control at the 48 h time mark BAL Cell Counts: Cell counts at 18 and 96 hours after OVA treatment did not differ among treatment groups. At 48 hours the number of eosinophils, neutrophils and lymphocytes were significantly increased in mice exposed to both high and low concentrations of DE. With DE exposure alone, only neutrophils were statistically increased in the high DE concentration. This indicates the combination exposure of DE and an antigen is essential to promote the development of allergic lung disease. BAL Cytokine Production: IL-6 production showed a dose-dependent and time-dependent increase, but was significantly increase in the high dose group at 96h. The high dose group saw a non significant increase in IL-10 levels over time. The greatest increase in IL-10 for the low dose group occurred 18 hours after OVA stimulation. Pulmonary Inflammation and Lung Injury: No differences among the groups were observed for macrophage, lymphocyte, neutrophil and eosinophil counts. Protein and LDH levels were not found to be increased in the BALF of any group. Gene Set Analysis: Pair wise comparisons revealed significant gene set difference between the high DE and control groups. Comparison of the high DE/OVA versus air/OVA showed significant changes in 23 gene sets, including genes involved in oxidative stress responses. The high DE/saline versus the air/saline showed significantly altered pathways. Altered pathways include those for cell adhesion, cell cycle control, apoptosis, growth and differentiation, and cytokine signaling. The results show that relatively short exposures to DE cause mild increases in immunologic sensitization to allergen. |

| Reference: Takizawa et al. (2003, 157039) Species: Human Cell Lines: Normal Small Airway Epithelial Cells and Bronchial Epithelial Cells (BET-1A) | Suspended DEP: collected using a 2,300-cc Isuzu diesel engine using standard diesel fuel at 1,050 rpm under a load of 6 torque. DE exposure in vitro (air exposure): collected using a 2,300-ml Isuzu diesel engine at 1,050 rpm. Composition: Fine particles: 1 mg/m ³ CO: 10.6ppm NO ₂ : 7.3ppm SO ₂ : 3.3ppm Particle Size: NR | Route: Cell Culture Dose/Concentration: Suspended DEP: varying doses from 0-50 µg/ml IL-13: varying doses from 0-25 ng/ml DE exposure in vitro (air exposure): 100µg/m ³ Time to Analysis: Cells were exposed to varying concentrations of suspended DEP for up to 24h. NF-κB: analyzed at 6h after suspended DEP exposure Air exposure at 0, 2, 4, 8 or 14h | Preliminary experiments indicated that DEP at 0.1- 50 µg/mL had no significant cytotoxicity to BET-1A cells and human bronchial epithelial cells (as analyzed by LDH levels). Eotaxin Production: (Eotaxin is a cc chemokine that plays a role in eosinophil accumulation in a variety of allergic disorders) Epithelial and BET-1A cells treated with suspended DEP or IL- showed a dose-dependent stimulatory effect on eotaxin release or production. Simultaneous exposure to 25ng/mL IL-13 and DEP depicted an additive effect for both cell types. Eotaxin mRNA: At 25 µg/mL, suspended DEP showed a time-dependent effect on eotaxin mRNA levels up to 12 h in both cell types. Extracted RNA from human bronchial epithelial cells exposed to varying doses of DEP showed a dose-dependent effect for both cell types (up to 25 µg/mL DEP) on eotaxin mRNA levels after 12h of exposure. IL-13 also induced a dose-dependent increase on eotaxin mRNA levels in cells in both cell types. Combination of IL-13 and DEP showed an additive effect on mRNA levels in BET-1A cells. DE exposure in vitro also showed a time-dependent stimulatory effect on eotaxin production in BET-1A cells. NF-κB / STAT6 Activation: (it has been suggested that NF-κB plays a role in the transcriptional regulation of eotaxin gene expression) Cells exposed to 1-25 µg/mL DEP for 6 h increased NF-κB. BET-1A cells treated with suspended DEP failed to activate STAT6 Effect of NAC and PDTC on Eotaxin mRNA Levels: (NAC and PDTC are antioxidant reagents with inhibitory effects on NF-κB activation) in BET-1A, both NAC and PDTC showed a dose-dependent inhibitory effect on DEP-induced eotaxin production. Both reagents also blocked DEP-induced eotaxin mRNA levels in BET-1A cells. NAC and PDTC did not suppress eotaxin production or eotaxin mRNA levels in IL-13 stimulated BET-1A cells. In addition pre-treatment with NAC attenuated NF-κB activation induced by DEP but had no effect on STAT6 induction by IL-13. These findings suggest that DEP stimulated eotaxin gene expression via NF-κB dependent, but STAT6-independent, pathways. |

| Reference: Tesfaigzi et al. (2005, 156116) Species: Rat Gender: Male Strain: Brown-Norway Age: 6wks | <p>PM: Wood smoke generated from a conventional wood stove that has a 0.5m³ firebox and a sliding gate air intake damper. The stove was operated over a 3-phase burn cycle that spanned 6 h. Fire was started (initiated exposure) with unprinted / unbleached newspaper and a mix of black and white oak.</p> <p>Wood smoke components: organic material, small amounts of elemental carbon and metals and associated analytes.</p> <p>Particle Size: 0.36 μm (MMAD)</p> | <p>Route: Whole-body Inhalation</p> <p>Dose/Concentration: PM: 1000 μg/m³</p> <p>Time to Analysis: Exposed to wood smoke or filtered air 6h/day for 70 consecutive days</p> <p>OVA IP injection immunization on days 2, 9</p> <p>OVA aerosol exposure 2h/day on days 67-70 following daily exposure to wood smoke or filtered air</p> <p>Sacrificed day 70</p> | <p>Body Weight and Respiratory Function: No difference in clinical signs or body weight was observed when comparing the two rat groups. The woodsmoke exposed group had a 45% lower dynamic lung compliance when compared to those exposed to the filtered air group before the methacholine challenge. Challenging the rats with methacholine caused a decrease in dynamic lung compliance in both groups, but the decrease was greater in the air-exposed group. At the highest dose of methacholine, the dynamic lung compliance in controls was similar to the baseline value of the smoke-exposed group. No significant differences in total pulmonary resistance were observed. Wood smoke exposed rats had a 10% increase in functional residual capacity than the air-exposed group.</p> <p>BAL Cell Counts and Cytokines: There was no difference in lymphocyte, eosinophil or neutrophils in the BALF of either group. There was an increase, though not statistically significant, in macrophages the wood smoke exposed group when compared to the filtered air group. In the BALF, IFN-α and IL-18 levels were significantly decreased, IL-4 and GRO-α levels were increased in rats exposed to wood smoke compared to filtered air. Serum IgE levels experienced a reduction trend in the wood smoke group, but it did not reach significance. Both groups showed mild signs of inflammation. The average eosinophils present in stained tissue was 21% higher in the wood smoke exposed group compared to the air exposed.</p> |
| Reference: Tomita et al. (2006, 097827) Species: Mouse Gender: Female Strain: C57BL/6J; AHR-deficient; mEH-deficient; ARNT floxed (loxP sequences inserted in Arnt gene); Tcell-specific ARNT-deficient Age: 7wks Weight: 20g | <p>DEP: two independent preparations fractionated into 13 different fractions based on acidic and basic functionality (one from light-duty, 4-cylinder diesel engine using standard diesel fuel from Dr. Kei Miwa and other generated from A4JB-type, Isuzu automobile, Japan)</p> <p>Individual PAH tested (Osaka, Japan):</p> <p>BbF = benzo[b]fluoranthene BeP = Benzo[e]pyrene IDP = Indeno[1,2,3-cd]pyrene BpPe = Benzo[ghi]perylene BaP = Benzo[a]pyrene BkF = Benzo[k]fluoranthene Per = Perylene DBA = Dibenzo[a,h]anthracene</p> <p>Particle Size: NR</p> | <p>Route: Intraperitoneal Injection</p> <p>Dose/Concentration: DEP, fractionated DEP or PAH compounds: 0.5 μg · 10 mg/kg bw in 50 μl of olive oil</p> <p>Time to Analysis: Single exposure, sacrificed 3d post exposure.</p> | <p>Effect on thymus: DEP treatment (10 mg/kg of body weight) caused severe atrophy of the thymus while the spleen and lymph nodes appeared normal. Three days following DEP treatment showed a marked reduction in thymus size. The total number of thymocytes was reduced by more than 70% mostly due to a massive reduction in DP cells (CD4+CD8+). DEP induced no significant alterations in the cell numbers of CD4/CD8 ratios in the spleen and lymph nodes.</p> <p>DEP Extracts: Only the WAC (carbonic acid fraction) and BE (weak basic fraction) did not produce a significant reduction in thymocyte numbers in vivo. Among the active fractions, 7 produced a marked selective loss of immature DP thymocytes, similar to the crude extract of DEP.</p> <p>PAH effects: Thymic involution was severely induced by the N and various other fractions. 7 out of the 8 PAH compounds were significantly effective in decreasing the number of thymocytes upon in vivo exposure. Only BpPe did not have an effect.</p> <p>AHR/ARNT and mEH deficient mice (BaP and DEP only): In the absence of AHR, BaP treatment did not result in a loss of thymocytes. Like DEP, BaP produced severe thymic involution in mEH-deficient mice. DEP-mediated thymic involution was significantly enhanced in mEH-deficient mice.</p> |

| Reference: Verstraeten et al. (2005, 096872) Species: Human Tissue/Cell Types: Monocyte-derived dendritic cells (Mo-DC) Cord blood samples of seven women were collected from umbilical vessels of placentas of normal, full-term infants. | DEP- SRM 2975 Particle Size: NR | Route: Cell Culture Dose/Concentration: DEP in varying concentrations: 0.2, 2, 20, 200, 2000 ng/mL LPS 100 ng/mL Time to Analysis: Cells were incubated for 24h and analyzed via flow cytometry. | Biological Markers: Exposure to DEP alone did not alter expression levels of HLA-DR, CD86 or CD83. Treatment with LPS alone caused a non-significant increase in all three markers when compared to the control. Treatment with DEP + LPS caused a significant increase in the expression of CD83 and a non-significant increased expression of HLA-DR and CD86. DEP + LPS induced a bell-shape dose-response curve on the expression of all three markers, with a dose of 20 ng/mL DEP + 100 ng/mL LPS causing the largest increase in upregulation. When only the results of the LPS-responsive donors (5 out of 7 blood cord samples) were included, the effects described above become more pronounced. |
| Reference: Walczak-Drzewiecka et al. (2003, 096784) Species: Mouse Cell Line: C1.MC/C57.1 (C57) Mast Cells | Metal and Transition Metal Ions: Sr^{2+} , Ni^{2+} , Cd^{2+} , Al^{3+} , Pb^{2+} Particle Size: NR | Route: Cell culture, Dose/Concentration: 0.1- 5 μmol Time to Analysis: 10min – 4h incubation before analysis | BHex Mediator Release in Mast Cells: Incubation with SrCl_2 , NiSO_4 , CdCl_2 or AlCl_3 resulted in a 2-5% release of B-hexoaminidase in mast cells. Incubation with a mixture of all these compounds induced a greater (11%) release in B-hexoaminidase, indicating there might be a additive effect. Cell Viability: Incubation of cells at concentrations and incubation time employed did not result in decrease in cell viability. Antigen-Mediated Mediator Release in Mast Cells: Al^{3+} and Ni^{2+} enhanced antigen-mediated release. 10-7 M AlCl_3 released 23% of B-hexoaminidase compared to antigen alone, which induced 11% release of B-hexoaminidase. Cd^{2+} , Sr^{2+} and Pb^{2+} enhanced antigen-mediated release to a lesser extent. Ni^{2+} , Al^{3+} , Sr^{2+} and Cd^{2+} depicted a dose-dependent relationship with antigen-mediated B-hexoaminidase release. Antigen-Induced Protein Phosphorylation: Addition of the antigen induced the anticipated phosphorylation of multiple proteins in C57 mast cells. The presence of Ni^{2+} and Pb^{2+} mediated an increase in phosphorylation of several of the proteins and Al^{3+} mediated a decrease in phosphorylation of multiple proteins (specifically the 56 and 37 kD bands). Antigen-Mediated Cytokine Secretion (IL-4): At certain concentrations all tested metal and transition metal ions were able to induce IL-4 secretion or enhance antigen-induced IL-4 secretion in mast cells, but no dose-dependent relationship was established. |

| Reference: Whitekus et al. (2002, 157142) Species: Mouse Cell Line: RAW 264.7 | DEP (light-duty, four-cylinder engine-4JB1 type, Isuzu Automobile, Japan; standard diesel fuel) (extracts) Particle Size: NR | Route: Cell Culture Dose/Concentration: 50 $\mu\text{g/mL}$ Time to Analysis: DEP extracts suspended in methanol and sonicated 20min. Centrifuged 10min. Dried DEP resuspended and stored -20°C . Cell cultures maintained 37°C . Exposed to antioxidants 5h. HO-1 western blot, determination of cellular GSH:GSSG ratios, carbonyl protein content, lipid hydroperoxides performed. | DEP significantly reduced the GSH:GSSG ratio. This effect was prevented by adding thiol antioxidants NAC or BUC. DEP increased lipid peroxide levels, but the addition of all antioxidants decreased these levels. DEP increased carbonyl groups. NAC, BUC, and luteolin reduced HO-1 expression. |
| Reference: Whitekus et al. (2002, 157142) Species: Mouse Gender: Female Strain: BALB/c Age: 6-8wks Weight: NR | DEP (light-duty, four-cylinder engine-4JB1 type, Isuzu Automobile, Japan; standard diesel fuel) (extracts) Particle Size: 0.5-4 μm | Route: Inhalation Dose/Concentration: 200, 600, 2000 $\mu\text{g/m}^3$ Time to Analysis: Exposed 1h/d 10d. Animals receiving OVA had 20min OVA exposure after DEP exposure. | DEP + OVA dose-dependently increased IgE and IgG1, being more effective than the OVA-alone treatment. This effect was significantly suppressed by thiol antioxidants NAC or BUC. DEP + OVA increased carbonyl protein and lipid peroxide over OVA. NAC or BUC suppressed lipid peroxide and protein oxidation. No general markers for inflammation were observed. |
| Reference: Witten et al. (2005, 087485) Species: Rat Gender: Female Strain: F344 Age: 8wks Weight: $\sim 175\text{g}$ | DEP (heavy-duty Cummins N14 research engine operated at 75% throttle) Particle Size: 7.234-294.27nm | Route: Nose-only Inhalation Dose/Concentration: Low- $35.3 \pm 4.9 \mu\text{g/m}^3$, High- $632.9 \pm 47.61 \mu\text{g/m}^3$ Time to Analysis: Exposed 4h/d, 5d/wk, 3wks. Pretreated with saline or capsaicin. | There were no differences for substance P. The low-exposure group had significantly less NK1. DEP reduced NEP activity. Plasma extraversion dose-dependently increased and was greatest in capsaicin animals. Respiratory permeability dose-dependently increased. IL-1B was significantly higher for the low-exposure group. IL-12 was significantly lower in the capsaicin high-exposure group. TNF- α increased in the high-exposure group and capsaicin low-exposure group. High exposure induced particle-laden AMs in the lungs, perivascular cuffing consisting of mononuclear cells, alveolar edema and increased mast cell number. Neutrophil and eosinophil influx was not seen. |
| Reference: Wong et al. (2003, 097707) Species: Rat Gender: Female Strain: F344/NH Age: $\sim 4\text{wks}$ Weight: $\sim 175\text{g}$ | DEP (Cummins N14 research engine at 75% throttle) (EC- 34.93-601.67 $\mu\text{g/m}^3$, OC- 1.90-11.25 $\mu\text{g/m}^3$, Sulfates 0.94-17.96 $\mu\text{g/m}^3$, Na- 4.07-4.78 ng/m^3 , Mg- 0.60-0.86 ng/m^3 , Ca- 5.05-10.66 ng/m^3 , Fe- 3.17-6.44, Cr- 0.68-1.31 ng/m^3 , Mn- 0.11-0.22 ng/m^3 , Pb- 0.97-1.24 ng/m^3) Particle Size: 7.5-294.3nm | Route: Nose-only Inhalation Dose/Concentration: Low- $35.3 \pm 4.9 \mu\text{g/m}^3$, High- $669.3 \pm 47.6 \mu\text{g/m}^3$ Time to Analysis: Exposed 4h/d, 5d/wk, 3wks. Pretreated with saline or capsaicin. | DEP dose-dependently increased plasma extraversion, which was further increased by capsaicin. In the high-exposure group, particle-laden AMs (which were reduced by capsaicin), inflammatory cell margination, perivascular cuffing with subsequent mononuclear cell migration and dispersal, increased mast cells, and decreased substance P were all seen. NK-1R was downregulated in the low-exposure group and upregulated in the capsaicin-pretreated high-exposure group. NEP decreased significantly for both groups. |

| Reference: Yanagisawa et al. (2006, 096458) Species: Mouse Gender: Male Strain: ICR Age: 5wks Weight: 25-28g | Washed DEP (carbonaceous core), DEP-OC(extracted organic chemicals) and Whole DEP Particles collected from: 4JB1-Type, four-cylinder, 2.74 L, Isuzu diesel engine, while operated on standard diesel fuel at 200g under a load of 10 torques. Particle Size: MMAD- 0.4 μ m | Route: IT Administration Dose/Concentration: 50 μ g/0.1L Time to Analysis: 1. Control- 0.1mL PBS 2. DEP-OC- 50 μ g 3. Washed DEP- 50ug 4. Whole DEP- 50ug DEP-OC + 50ug Washed DEP5. OVA- 1 μ g = 6. DEP-OC- 1 μ g + OVA 7. Washed DEP- 50 μ g + OVA 8. Whole DEP- 50 μ g DEP-OC + 50 μ g Washed DEP + OVA All groups received OVA or PBS every 2 wks for 6 wks and the PM component or PBS once a week for 6 wks. | BAL Analysis: DEP-OC + OVA caused a significant increase in PMN infiltration in the BAL compared to the control Exposure to Whole DEP+ OVA caused PMN count to rise further Macrophages: OVA alone DEP-OC +OVA, Washed DEP + OVA and Whole DEP + OVAall caused a significant increase in macrophages compared to the control. Lung Histology: Exposure to OVA, Washed DEP, DEP-OC and Whole DEP caused a slight increase in PMNs, mononuclear cells and goblet cell proliferation. Treatment with all three DEP groups + OVA caused a significant increase in mononuclear cells, PMNs and goblet cell proliferation. Whole DEP + OVA had the greatest impact. Th1 and Th2 Cytokine Expression: Washed DEP+OVA caused a significant increase in IFN- α compared to control, whereas Whole DEP+OVA caused a significant decrease compared to control. No significant differences in IL-2 and IL-4 levels were seen among groups. DEP-OC + OVA and Whole DEP + OVA caused significant increases in IL-5 compared to control and compared to OVA Whole DEP+OVA caused significant increase in IL-13 compared to control Eotaxin and MIP-1α Expression: OVA increased eotaxin levels and DEP-OC+OVA caused a more significant increase in eotaxin. Whole DEP alone caused a significant increase in MIP-1 α and Whole DEP+OVA caused an even greater increase in MIP-1 α . IgG1 Levels: Exposure to DEP-OC+OVA caused an increase in IgG1 and exposure to Whole DEP+OVA caused greater elevation in IgG1 levels. |
| Reference: Yang et al. (2003, 087886) Species: Mouse Gender: Female Strain: B6C3F1 Age: 6-8wks | DEP- SRM 1650 Particle Size: MMAD- 0.5mm | Route: IT Aspiration Dose/Concentration: 1, 5, or 15 mg DEP/kg body weight Time to Analysis: Mice exposed to 1, 5, or 15 mg DEP/kg of body weight for either 3 times in 2 wks or 6 times in 4 wks. | Toxicity of DEP Exposure: DEP did not have a significant effect on body, liver or spleen weight. The highest dose of DEP caused an increase in lung weight and lung weight relative to body weight. None of the hematological parameters were significantly different in the mice exposed for 2wks; in the 4 wk group there was a significant decrease in platelet counts in mice exposed to 15mg/kg. DEP Exposure on Spleen IgM AFC: DEP exposure for 2-weeks induced a dose-dependent decrease in spleen AFC in response to sRBC immunization. Mice exposed to 15 μ g/kg depicted a 35% reduction in total spleen activity. In the group exposed to DEP for 4 weeks, the decrease in AFC was not significantly different than the control. DEP Exposure on Spleen Cell Number/Lymphocyte Counts: Exposure for 2 or 4 weeks did not affect total number of nucleated splenocytes. DEP caused a 30% reduction in total T cells. The number of B cells were not significantly affected. DEP Exposure on Spleen T-Cell Function: (evaluated in 2 week exposure group only) DEP induced a dose-dependent decrease in spleen cell proliferation to ConA. DEP did not affect spleen cell proliferation in response to anti-CD3 mAb. Production of IL-2 in response to ConA was reduced in a dose-dependent manner by DEP exposure. IFN- α production was decreased by exposure to DEP. IL-4 production was not measurable. |

| Reference: Yin et al. (2005, 088133) Species: Rat Gender: Male Strain: Brown-Norway (BN/CrIBR) Age: NR Weight: 200-250g | DEP = SRM 2975 (NIST) <i>Listeria</i> Particle Size: NR | Route: Nose-only inhalation (DEP), IIT instillation (<i>Listeria</i>) Dose/Concentration: 100,000 CFU (<i>Listeria</i>); 21.2 + 2.3 mg/m ³ (DEP) Time to Analysis: DEP exposure for 4 h/d for 5d; infection with <i>Listeria</i> 7d postexposure; sacrifice 3 and 7d postinfection | Lung deposit: Estimated mean lung deposit of DEP = 406 + 29 µg/rat DEP prolonged growth of bacteria in lung Alveolar Macrophage (AM) response: DEP significantly inhibited <i>Listeria</i> -induced IL-1B secretion at d7 and TNF-α snf IL-12 at both d3 and d7. IL-10 production was enhanced at d7. T-Lymphocyte response: DEP significantly reduced the development of T cells in response to <i>Listeria</i> infection. These lymphocytes displayed increased production of IL-6 at d7, but significantly diminished levels of IL-10, IL-2 and IFN-α. |
| Reference: Yin et al. (2004, 097685) Species: Rat Gender: Male Strain: Brown-Norway (BN/CrIBR) Age: NR Weight: 200-250g | DEP = SRM 2975 (NIST) <i>Listeria</i> Particle Size: NR | Route: Inhalation Exposure (DEP) IT instillation (<i>Listeria</i>) Dose/Concentration: 20.62 + 1.31 mg/m ³ (DEP). 100,000 CFU <i>Listeria</i> Time to Analysis: DEP exposure for 4 h/d for 5d; inoculation with bacteria 2h postexposure; sacrifice 3, 7, 10d postinfection | Lung deposit: Estimated mean lung deposit of DEP = 389 + 25 µg/rat Pulmonary responses and bacterial clearance: DEP significantly augmented <i>Listeria</i> -induced neutrophil infiltration, lung CFU and recoverable alveolar macrophages (AM) at all times post-infection. LDH activity was increased 3d post-infection. Bacterial count in DEP exposed rats remained significantly higher through d7. Cytokine production by AM: DEP exposure significantly lowered <i>Listeria</i> -induced production of IL-1B, TNF-α and IL-12. Production of IL-10 was strongly augmented. T-lymphocyte responses: DEP moderately but not significantly lowered the total number of lymphocytes, CD4 ⁺ cells and lymphocyte IL-10 production. <i>Listeria</i> -induced T-cell development was strongly inhibited, as were the development of CD8 ⁺ cells, IL-12 production and IFN-α secretion. DEP and <i>Listeria</i> exposure showed and increased production of IL-6 at d3 and d7 post-exposure. |
| Reference: Yin et al. 2007 Species: Rat Gender: Male Strain: Brown-Norway (BN/CrIBR) Age: NR Weight: 225-250g | DEP = SRM 2975 eDEP = organic DEP extract wDEP = washed DEP CB = carbon black Particle Size: DEP: median diameter- 19.4 µm, surface area- 91 µ ² /g; CB: 0.1-0.6 µm | Route: IT Instillation of <i>Listeria</i> . Treatment after AM cell isolation Dose/Concentration: DEP: 10, 50, 100 µg/mL; CB: 50 µg/mL Time to Analysis: Sacrifice postinfection or no infection. AM isolated. DEP or CB treatments for 1, 4, 16, 24h. | AM Phagocytosis: None of the DEP or CB treatments were cytotoxic or affected the number of adherent cells. 10-100 µg/mL. DEP significantly decreased AM phagocytosis in a concentration- and time-dependent manner, with increased concentration and time decreasing activity. Bacterial Activity: The inhibition of AM bactericidal activity by DEP was time- and concentration-dependent. eDEP and wDEP inhibited the AM bactericidal activity but were less effective than DEP. The CB treatment was not significant. Cytokine Secretion by AM: DEP and eDEP concentration-dependently decreased TNF-α, IL-1B and IL-12, but increased IL-10. wDEP and CB did not show a significant effect. Cytokine Secretion by Lymphocytes: DEP and cDEP concentration-dependently decreased IL-2 and IFN-α. wDEP and CB had little effect, except high concentrations of wDEP decreased IFN-α. |

| Reference: Yin et al. (2004, 087983) Species: Rat Gender: Male Strain: Brown-Norway (BN/CrIBR) Age: NR Weight: 225-250g | DEP = SRM2975 eDEP = organic DEP extract wDEP = washed DEP CB = carbon black Particle Size: DEP- NR, CB- 0.1-0.6 μm | Route: IT Instillation of <i>Listeria</i> . Treatment after AM cell isolation Dose/Concentration: 50 $\mu\text{g/mL}$ (DEP or CB) Time to Analysis: Killed 7d postinstillation. AM isolated then incubated. DEP treatments for up to 24h at 37 degrees. | DEP-induced ROS production: ROS was induced by DEP or eDEP and inhibited by eDEP with ANF or NAC. eDEP induction of ROS was time-dependent. wDEP or CB did not induce ROS. DEP-induced HO-1 expression: DEP- or eDEP-induced HO-1 expression was inhibited by ANF, NAC or SB203580. wDEP or CB did not induce ROS. DEP or eDEP exposure resulted in a 2.5- to 3-fold induction of HO-1 expression in uninfected AM. eDEP-modulated cytokine production: eDEP exposure resulted in a time-dependent increase in LPS-stimulated IL-10 or TNF- α production, and both were inhibited by ANF or NAC. wDEP did not affect either. SOD pretreatment attenuated eDEP-upregulated HO-1 expression, inhibited IL-10, and reversed eDEP inhibition of IL-12. Znpp decreased IL-10. |
| Reference: Yin et al. (2003, 096127) Species: Rat Gender: Male Strain: Brown-Norway (BN/CrIBR) Age: NR Weight: 200-250g | DEP = SRM 1650a <i>L. monocytogenes</i> Particle Size: NR | Route: Nose-only Inhalation (DEP). IT Instillation (<i>Listeria</i>) Dose/Concentration: 50 or 100 mg/m^3 (DEP); 100,000 bacteria per 500 μL sterile saline (<i>Listeria</i>) Time to Analysis: DEP exposure for 4h. Bacterial inoculation. Sacrificed 3, 7d postexposure. | Lymphocyte population: DEP-alone exposure increased total lymphocytes, T cells and T-cell subsets. Elevated cell counts in the combined exposure were DEP dose-dependent, with the 100 mg/m^3 treatment having significant increases in the cell number and $\text{CD}^{8+}/\text{CD}^{4+}$ ratio. IL-2: DEP exposure in noninfected rats at both doses increased IL-2 in the 24h culture and decreased IL-2 in the 48h culture. The increase in IL-2 at 3 days postinfection was not significant. DEP exposure increased IL-2R α in response to ConA stimulation. DEP-treated infected rats had increases in ConA-inducible $\text{CD}^{4+}/\text{IL-2R}\alpha^+$ and $\text{CD}^{8+}/\text{IL-2R}\alpha^+$. IL-6: IL-6 production was dose-dependent in DEP-treated uninfected rats and infected rats. The combined exposure produced less IL-6 than the DEP-alone or <i>Listeria</i> -alone treatments. IFN-γ: DEP decreased IFN- γ at 3 days postexposure, but increased at 7 days postexposure in a dose-dependent manner. Uninfected DEP-treated rats did not substantially respond to HKLM. HKLM-induced IFN- γ production is strongly inhibited at all tested DEP doses. |
| Reference: Zelikoff et al. (2003, 039009) Species: Rat Gender: Male Strain: Fischer 344 Age: 7-8mo Weight: NR | CAPS = concentrated ambient $\text{PM}_{2.5}$ from New York City <i>S.pneumoniae</i> Particle Size: MMAD- 0.4 μm | Route: Nose-only Inhalation (CAPS) IT Instillation (<i>S.pneumoniae</i>) Dose/Concentration: CAPS: Study 1- 60-600 $\mu\text{g/m}^3$, Mean- 345 $\mu\text{g/m}^3$; Study 2- 65-150 $\mu\text{g/m}^3$, Mean-107 $\mu\text{g/m}^3$, (<i>S.pneumoniae</i> 2-4 $\times 10^7$) Time to Analysis: Study 1: Uninfected rats exposed to air or CAPS for 3h. Sacrificed 3, 24, or 72h postexposure or IT instilled 4, 24, 72, 120h and sacrificed 4, 24, 72h postinfection Study 2: Infection with bacteria. Exposed 48h later to CAPS or filtered air for 5h. Sacrifice 9, 18, 24, 72, 120h postexposure. | Study 1: CAPS did not effect cell numbers, viability, profiles, lavageable LDH activity, total protein, or total circulating WBC counts. Exposure to CAPs prior to infection significantly increased PMN and decreased lymphocytes. WBC levels returned to control levels by 4h postinfection. CAPS had no effect on circulating monocyte values. CAPS significantly increased bacterial burdens at 24h, but thereafter the burden decreased to below control levels. Study 2: In CAPS exposed rats, PMN decreased, Pam increased, and the cytokines TNF- α , IL-1B and IL-6 decreased. Lymphocytes and monocytes were unaffected. Bacterial burdens in CAP-exposed rats were about 10% greater than air controls at 9h and > 300% greater at 18h. CAPS significantly increased the percent of affected lung area and severity of infection. |

| Reference: Zelikoff et al. (2002, 037797) Species: Rat Gender: Male Strain: Fischer 344 Age: 7-9m Weight: NR | Ambient NYC PM Single transition metals of Fe, Mn, Ni <i>Streptococcus pneumoniae</i> Particle Size: NYC PM: PM _{2.5} Fe ²⁺ , Mn ²⁺ , Ni ²⁺ : 0.4 µm (MMAD) | Route: NYC PM, single transition metals: Nose-only inhalation <i>S. pneumoniae</i> : IT instillation Dose/Concentration: 15-20 x 10 ⁶ (<i>S.pneumoniae</i>); Single metals/NYC PM: 65-90 µg/m ³ Time to Analysis: Infection/no infection followed by 5h exposure to NYC PM or single transition metal. Sacrifice 4, 5, 9, 18, 24, and 120h after exposure | CAPs exposure to infected rats significantly increased pulmonary bacterial burdens of <i>S. pneumo</i> in a time-dependent manner. At 9h, 18h, 24h, and 5d after CAPs exposure, bacterial burdens were 10%, 300%, 70% and 30% above controls. Uninfected rats exposed to the single transition metals showed significant alterations in PMNs and lymphocytes values at 1h postexposure. Exposure to Fe of uninfected rats significantly increased superoxide anion production by pulmonary macrophages. Uninfected rats exposed to inhaled Fe significantly reduced B-lymphocyte proliferation at 48 h, but did not affect T-lymphocyte production. Inhaled Ni, for the uninfected, significantly decreased T-lymphocyte production at 18h, and did not affect B-lymphocyte production. Inhalation of Fe by infected rats facilitated an increase in bacterial numbers while Ni inhibited bacterial clearance. Inhaled Fe by infected also significantly decreased PMNs and lymphocyte numbers by 35% and increased pulmonary macrophage numbers by 29% when compared to the air exposed group. Results demonstrated that inhalation of Fe altered innate and adaptive immunity in uninfected hosts, and both Fe and Ni reduced pulmonary bacterial clearance in previously infected rats. |
| Reference: Zhong et al. (2006, 093264) Species: Mouse Gender: Male Strain: BALB/c Age: 6-8wks Weight: NR Cell Line: J774A.1 | CAPs: Concentrated Air Particles (Boston, MA) Urban air particles (UAP) SRM1649 (Washington, DC) Titanium Oxide (TiO ₂) (Baker Chemicals, Phillipsburg, NJ) Carbon Black (CB) (Sigma, St. Louis, MO) Particle Size: UAP = NR; TiO ₂ /CB = NR; CAPs: αPM _{2.5} <i>Streptococcus pneumoniae</i> : strain ATCC6303 | Route: Cell Culture Dose/Concentration: NR, 100 µg/mL Time to Analysis: Pre-treated CAPs cells exposed to CAPs for 1h. All cells, IFNy-primed AMs, unprimed AMs, and J774A.1, exposed to bacteria for 1h. Binding measured 15h after bacteria exposure. Ingestion measured 2h after bacteria exposure. Rate and number of killed bacteria measured 2h after bacteria exposure. | Binding, internalization and killing of bacteria: CAPs significantly increased binding of bacteria by IFNy-primed AMs, normal AMs and J774A.1. CAPs decreased internalization and absolute number of bacteria killed by macrophages of all types. The rate of killing of internalized bacteria was similar in the presence or absence of CAPs; however, CAPs did cause a decrease in the absolute number of bacteria killed by all three types of macrophages, due to the decrease in internalization. Effects of other particles: TiO ₂ and CB had no effect on J774 binding or internalization of <i>S. pneumo</i> . TiO ₂ and CB's effects on primed and unprimed AMs were not reported. Testing with UAPs, however, showed effects similar to those observed with CAPs. Soluble components: The soluble fraction of CAPs, especially iron, is responsible for decreased internalization. |

Table D-5. Effects of the central nervous system.

| Reference: Calderón-Garcidueñas et al. (2003, 156316) Species: Dog Gender: Male, Female Strain: Mixed breed Age: 7d-10yrs Weight: 349 ± 116g – 20kg | Urban Air (Mexico City-high PM region, Tlaxcala- low PM region) (PM, Pb, volatile organic compounds, formaldehyde, acetaldehyde, mutagenic PM, alkane hydrocarbons, Ni, V, Mn, Cr, peroxyacetyl NO ₂ ² , LPS, endotoxins) Particle Size: PM: 2.5, 10 µm | Route: Ambient Air Exposure Dose/Concentration: Mexico City: PM ₁₀ : 78 µg/m ³ , PM _{2.5} : 21.6 µg/m ³ , Pb in TSP: < 0.4 µg/m ³ Time to Analysis: Dogs raised in house or outdoor-indoor kennel. Lifetime exposure. | Mexico City dogs had significantly greater apurinic and apyrimidic sites in the olfactory bulb and hippocampus. Histopathological changes in the respiratory and olfactory epithelium were greatest in Mexico City dogs. Mexico City dogs also had greater immunoreactivity than the controls for NF-κB, iNOS, cyclooxygenase-2, glial fibrillary acidic protein, ApoE, amyloid precursor product and B-amyloid. |
| Reference: Campbell et al. (2005, 087217) Species: Mouse Strain: BALB/c Age: 7wks | CAPs from Los Angeles, lacking reactive organic and H ₂ O soluble gases, O ₃ , NO _x , SO _x Particle Size: F + UF: < 2.5 µm; UF: < 0.18 µm | Route: Whole-body Exposure Dose/Concentration: 20-fold concentration of near highway ambient air, avg UF concentration: 282.5 µg/m ³ , avg F concentration: 441.7 µg/m ³ Time to Analysis: 4h/d, 5d/wk for 2wks | Mice were challenged with OVA prior to exposure and 1 and 2 weeks following exposure, and then brains were assayed. F + UF and UF exposure increased NF-κB DNA binding in brain. TNFα increased with F + UF. IL-1α increased with UF and F + UF. This suggests a possible link between PM exposure and neurodegenerative disease processes. |
| Reference: Che et al. (2007, 096460) Species: Rat Strain: Sprague-Dawley Gender: Male and Female Age: 9wks Weight: 190-220g | Gasoline exhaust (collected from 1996 Guangzhou passenger car with Dongfeng Gasoline Series 155 kw engine and no exhaust catalytic converter fuelled with 90-octane lead-free gasoline from China Petroleum). Particle Size: NR | Route: IT Instillation Dose/Concentration: 5.6, 16.7, or 50.0 L/kg, final volume 0.3 mL/rat Time to Analysis: 1/wk for 4wks. Parameters measured 24h post last instillation. | A dose-dependent increase was observed in brain DNA damage starting at 5.6 L/kg. Increase in lipid peroxidation and carbonyl protein was also observed at 50 L/kg. Decrease in brain SOD occurred at all exposures. GPx activity was unchanged with exposure. This suggests an association between gasoline exhaust and oxidative damage to the brain. |
| Reference: Kleinman et al. (2008, 190074) Species: Mouse Gender: Male Strain: ApoE ^{-/-} Age: 6wks Weight: NR | CAPs (Los Angeles, CA) (OC, EC = ~ 50%; sulfate, nitrate ~ 11%) Particle Size: NR | Route: Whole-body Exposure Chamber Dose/Concentration: High dose: Mass concentration- 114.2 µg/m ³ , Concentrated factor- 15.4 ± 3.2; Low dose: Mass concentration: 30.4 µg/m ³ , Concentrated factor- 4.1 ± 0.9 Time to Analysis: Exposed 5h/d, 3d/wk, 6wks. Killed 24h postexposure. | Activated AP-1 dose-dependently increased. Activated NF-κB significantly increased with the high CAPs dose. GFAP (which represented activated astrocytes) and activated JNK significantly increased with the low CAPs dose. |
| Reference: Liu et al. (2005, 088650) Species: Rat Strain: Wistar Gender: Male Age: 8wks | CAPs from Taiyuan, China Particle Size: < 2.5 µm | Route: IT Instillation Dose/Concentration: 0, 1.5, 7.5, or 37.5 mg/kg, final volume 0.2 mL/rat Time to Analysis: Assayed 24h following instillation | In the brain, SOD and CAT activity were significantly decreased at the 2 highest doses; GSH levels were significantly decreased at the highest dose. This suggests an association between PM exposure and oxidative damage mediated by prooxidant/antioxidant imbalance or high levels of free radicals. |
| Reference: Sirivelu et al. (2006, 111151) Species: Rat Gender: Male Strain: Brown Norway Age: 12-13wks | CAPs from Grand Rapids, MI Particle Size: < 2.5 µm | Route: Whole-body Exposure Dose/Concentration: 500 µg/m ³ Time to Analysis: 8h, assayed at 24-h PE | PVN: CAPs alone or with OVA increased NE. MPA: CAPs increased Da when treated with OVA while no changes in NE, 5-HIAA and DOPAC were observed. Arcuate nucleus: OVA sensitization increased NE levels. OB: CAPs and OVA increased NE levels, but no changes in Da, DOPAC, or 5-HIAA were observed. Other areas: No differences in other areas of hypothalamus, substantia nigra, or cortex were observed. CAPs alone or with OVA increased serum corticosterone. These results suggest that CAPs can cause region-specific modulation of neurotransmitters in brain and that the stress axis may be activated causing aggravation of allergic airway disease. |

| Reference: Veronesi et al. (2001, 015977) Species: Mouse Strain: ApoE ^{-/-} or C57Bl/6 Age: Young adults | CAPs from Tuxedo, NY Particle Size: < 2.5 µm | Route: Whole-body Inhalation Dose/Concentration: Varied daily, PM _{2.5} concentrated 10-fold, producing an average of 113 µg/m ³ . Time to Analysis: 6h/d, 5d/wk for 4m | CAPs-exposed ApoE ^{-/-} mice had an 29% reduction in TH-stained neurons and a 8% increase in GFAP staining compared to air-exposed ApoE ^{-/-} . No differences were seen in C57 mice. The results suggest that ApoE ^{-/-} mice, characterized by increased brain oxidative stress, are susceptible to PM-induced neurodegeneration. |
| Reference: Veronesi et al. (2005, 087481) Species: Mouse Gender: NR Strain: ApoE ^{-/-} , C57Bl/6 Age: NR Weight: NR | CAPs (Tuxedo, NY) Particle Size: 2.5 µm | Route: Whole-body Exposure Dose/Concentration: Average: 110 µg/m ³ Time to Analysis: Exposed 6h/d, 5d/wk, 4m. | Dopaminergic neurons significantly decreased in CAPs-exposed mice compared to the controls. CAPs caused significantly more astrocytes (as measured by GFAP staining) in the nucleus compacta compared to the controls. |
| Reference: Win-Shwe et al. (2008, 190146) Species: Mouse Gender: Male Strain: BALB/c Age: 7wks Weight: NR | DEP (Nanoparticle-rich – NPDE; 81-diesel engine, steady-state condition, 5h/d, 2000rpm, 0 Nm) (CO, CO ₂ , NO, NO ₂ , SO ₂) Particle Size: Diameter: 26.21 ± 1.50nm | Route: Whole-body Exposure Chamber Dose/Concentration: 148.86 ± 8.44 µg/m ³ Time to Analysis: Exposed to NPDE or filtered air 5h/d, 5d/wk, 4wks. Some mice ip injected with lipoteichoic acid (LTA) 1X/wk, 4wks. Morris water maze behavioral test: 3d acquisition, 2d probe trial. | Mice in the LTA + NPDE group had significantly longer mean escape latencies, indicating impaired acquisition of spatial learning. NPDE directly increased NR1 and TNF-α. LTA + NPDE increased NR2A, NR2B, and IL-1B, however LTA was primarily responsible for the increases. |
| Reference: Zanchi et al. (2008, 157173) Species: Rat Gender: Male Strain: Wistar Age: 45d | ROFA from Universidade de São Paulo, Brazil Particle Size: 1.2 ± 2.24 µm (MMAD) | Route: Intranasal Instillation Dose/Concentration: 20µg/ 10µl saline Time to Analysis: 30d | Exposed rats had increased lipid peroxidation in striatum and cerebellum. This could be reversed with N-acetylcysteine treatment. ROFA treatment altered motor activity shown by decreased general exploration and peripheral walking, and was not prevented by NAC. Results suggests that chronic ROFA induces behavioral changes and brain oxidative stress. |

Table D-6. Reproductive and developmental effects.

|---|---|---|---|
| Reference: Fedulov et al. (2008, 097482) Species: Mouse Gender: Female (pregnant), Offspring: NR Strain: BALB/c Age: NR Weight: NR | DEP Carbon black (CB) TiO ₂ Particle Size: NR | Route: Intranasal Insufflation Dose/Concentration: DEP, TiO ₂ : 50 µg in 50 µL, 50 µg/mouse; CB: 250 µg in 50 µL Time to Analysis: Particle samples baked 3h. Protocol 1a: Pregnant mice treated with DEP or TiO ₂ . Analyzed 19 or 48h later. Protocol 1b: Pregnant mice DEP, TiO ₂ or CB treated day 14 of pregnancy. 4d-old offspring i.p. injected with OVA + alum. 12-14d-old exposed aerosolized OVA. | DEP increased BAL PMN counts in normal and pregnant mice. In pregnant mice, DEP and TiO ₂ increased IL-1B, TNF-α, IL-6 and KC compared to nonpregnant controls. Offspring of DEP, CB or TiO ₂ exposed mice had increased AHR and airway inflammation. TiO ₂ exclusively altered the expression of 80 genes in pregnant mice. |
| Reference: Fujimoto et al. (2005, 096556) Species: Mouse Strain: Slc:ICR Gender: Females (pregnant mice and fetuses) Age: NR (pregnant females), 14d of gestation (fetuses) | DE: generated by 2369 cc diesel engine at 1050 rpm at 80% load with commercial light oil Particle Size: 0.4 µm (MMAD) | Route: Inhalation Chamber Dose/Concentration: 0.3, 1.0 or 3.0 mg DEP/m ³ Time to Analysis: 12h/d, 7d/wk from 2d post coitum to 13dpc. Sacrificed 14dpc. mRNA expression examined in female fetuses. | Significant increase in absorbed placentas were observed in the 0.3 and 3.0 concentration. A decrease in absorbed placentas was observed for the 1.0 concentration. Increased inflammatory cytokine mRNA in placentas from exposed offspring were observed. An increased number of absorbed placentas in DE-exposed offspring were seen. |

| Reference: Hougaard et al. (2008, 156570) Species: Mouse Strain: C57Bl/6 Gender: Pregnant females, male and female offspring Age: 12 & 16 wks (female offspring), 13 & 17 wks (male offspring) | DEP(SRM2975) Particle Size: 90 m ² /g (SA) | Route: Whole-body Inhalation Dose/Concentration: 20 mg DEP/m ³ Time to Analysis: Exposed 1h/d from gestation days 7-19. Mice separated for behavioral testing on PND 22 (day of delivery is PND 0). Behavioral testing at 12, 16 wks for female offspring and 13, 17 wks for male offspring. | Body wt of exposed Unchanged at birth. Body wt decreased At weaning. T4 Unchanged dams & Pups @ weaning. At 2 months, exposed Female pups required Less time to locate Platform in spatial Reversal task of Morris Water maze. |
| Reference: Hougaard et al. (2008, 156570) Species: Mouse Gender: Female (pregnant), Offspring- male, female Strain: C57BL/6 Age: NR Weight: NR | DEP (SRM 2975) Particle Size: Surface area: 90mg ² /g. Density: 2.1g/cm ³ , MMAD: 240nm | Route: Inhalation Chamber Dose/Concentration: 19.1 ± 1.13mg DEP/m ³ Time to Analysis: Pregnant dams exposed GD 7-19, 1h/d. GD 20 named PND 0 for pups. Weights recorded, 1 pup from each group sacrificed PND 2. Weights recorded PND 9. PND 22 1 male and female removed from each group for behavioral testing. Dams and remaining offspring sacrificed PND 23 or 24. | DEP females gained more weight during gestation. Generally, DEP pups weighed less. No significant DNA damage was measured, but DEP caused slightly higher IL-6, MCP-1, and MIP-2. Plasma thyroxine levels as well as learning and memory were similar amongst the groups. |
| Reference: Huang et al. (2008, 156574) Species: Rat Gender: Male (adults), male and female (fetuses) Strain: Wistar Age: 8 wks (male adults), 20d of gestation (fetuses) | ME: Motorcycle Exhaust (generated from 1992 Yamaha cabin motorcycle with two-stroke 50 cc engine). Particle Size: NR | Route: Nose-only Inhalation Dose/Concentration: 1: 10 and 1: 50 dilutions Time to Analysis: 2h/d (1h in morning and 1h in afternoon), for 5 consecutive days/wk, for 4 wks (1:50, 1:10 dilutions) and 2 wks (1:10 dilution). Male mated with untreated females. Pregnant females sacrificed on 20d of gestation. Male and female fetuses observed. | After exposure, decreased body weight and testicular spermatid number were observed. 1: 10 ME exposure for 4 weeks (no recovery) decreased testicular weight and increased the inflammatory cytokine mRNA. Glutathione system and LipidPeroxidation were not affected. |
| Reference: Lichtenfels et al. (2007, 097041) Species: Mouse Gender: Male and Female Strain: Swiss Age: NR | Ambient air in São Paulo, Brazil Particle Size: NR | Route: Ambient Air Exposure Dose/Concentration: NA Time to Analysis: Males housed in open-top chambers for 24h/d, everyday for 4m, beginning 10d after birth. Males mated to non-exposed females immediately following exposure. Males sacrificed immediately following mating. Pregnant females remain in chamber and sacrificed on 19d of pregnancy. | Decreased testicular, epididymal sperm counts, decreased number of germ cells, and decreased elongated spermatids were observed. Decreased SSR, and a sex ratio shift (fewer males) also occurred after exposure. |
| Reference: Mauad et al. (2008, 156743) Species: Mouse Gender: Male, Female Strain: BALB/c Age: 10d Weight: Parental: 21.4 ± 4.0 – 26.3 ± 2.8g; 15d-old offspring: 7.8 ± 1.1 – 9.0 ± 1.0g; 90d-old offspring: 20.3 ± 2.3 – 27.4 ± 1.8g | PM (busy traffic street São Paulo, Brazil; Aug. 2005-April 2006) (NO ₂ , SO ₂ , CO) Particle Size: Diameter: 2.5, 10 µm | Route: Ambient Air Exposure Dose/Concentration: PM _{2.5} : filtered chamber- 2.9 ± 3.0 µg/m ³ , nonfiltered chamber- 16.9 ± 8.3 µg/m ³ ; Outdoor concentration: PM ₁₀ - 36.3 ± 15.8 µg/m ³ , CO- 1.7 ± 0.7ppm, NO- 89.4 ± 31.9 µg/m ³ , SO ₂ - 8.1 ± 4.8 µg/m ³ Time to Analysis: Nonfiltered exposure 24h/d 4m. Mated at 120d exposure. After birth, 30 females and offspring transferred to filtered or nonfiltered chamber. Killed 15 or 90d of age. | Mild foci of macrophage accumulations containing black dots of carbon pigment occurred in the alveolar areas on 90d-old mice. Surface-to-volume ratio decreased from 15 to 90d of age and was higher in mice exposed to air pollution. PM exposure reduced inspiratory and expiratory volumes at higher levels of transpulmonary pressure. |

|---|--|--|---|
| Reference: Mohallem et al. (2005, 088657) Species: Mouse Strain: BALB/c Gender: Female Age: 10wks, 10d | Filtered or ambient air in downtown Sao Paulo situated at crossroads with high traffic density (predominant source of air pollution is automotive). Component concentrations in ambient air: CO: 2.2 ± 1.0 ppm; NO ₂ : 107.8 ± 42.3 $\mu\text{g}/\text{m}^3$; PM ₁₀ : 35.5 ± 12.8 $\mu\text{g}/\text{m}^3$; SO ₂ : 11.2 ± 5.3 $\mu\text{g}/\text{m}^3$ Component concentrations in filtered air: NO ₂ : 19.5 ± 2.8 $\mu\text{g}/\text{m}^3$; PM ₁₀ : 24.1 ± 8.1 $\mu\text{g}/\text{m}^3$ Particle Size: NR | Route: Whole-body Inhalation Dose/Concentration: 50 L/m (polluted chamber) Time to Analysis: Exposed for 24 h/7 days/wk for 4 mo. Newborns mated after reaching reproductive age of 12 wks. All pregnant females sacrificed between 19 th and 20 th day of pregnancy. | No effects in adult exposed animals. Increased implantation Failure of neonatal Exposed-dams. Sex ratio, # of Pregnancies, Resorptions, Fetal deaths, And fetal placenta Weights unchanged After neonatal Ambient air exposure. |
| Reference: Mori et al. (2007, 096564) Species: Mouse Strain: C57/BL Gender: Male Age: 6wks | DEP: generated by 4-cylinder diesel engine Particle Size: NR | Route: Dorsal Subcutaneous Instillation Dose/Concentration: 0.2 ml (of 1.1mg/ml or 0.37 mg/ml) Time to Analysis: 2x/wk for 10 wks. Parameters measured 1wk post last instillation. | cDNA library screen after Sub-cut. Injection Found identified activated Clones related to Prostanoids & Arachadonic Acid (Platg2c2c, Acs16) & sperm Production (Stk35). Route of exposure. Unconventional. |
| Reference: Ono et al. (2007, 156007) Species: Mouse Strain: ICR Gender: Pregnant females, male offspring Age: NR (pregnant females), 12 wks (offspring) | DE: generated from 4-cyl diesel Isuzu engine at 1500 rpm using standard diesel fuel. Particle Size: NR | Route: Inhalation (further details NR) Dose/Concentration: Time to Analysis: Exposed from 2d post coitum to 16dpc. Parameters for male offspring measured on days 8, 16, 21, 35, 84 and sacrificed at 84d. | PND 8 and 16 male repro accessory gl weight decreased. PND 21decreased serum T; PND 84 increased serum T. FSHr, sTAR mRNA Decreased PND 35 & 84. Rel. testis and epididymal wt unchanged. Sertoli cell degeneration |
| Reference: Ono et al. (2007, 156007) Species: Mouse Strain: ICR Gender: Male offspring, Pregnant females Age: 12wks (male offspring) | DE: generated from 4JB-2type, light duty 3060 cc 4-cyl Isuzu diesel engine under 1500 rpm Particle Size: NR | Route: Whole-body Inhalation Dose/Concentration: 1.0 mg DEP/m ³ Time to Analysis: Pregnant females exposed from 2d postcoitum- 16dpc. Without undergoing further exposure, male offspring sacrificed at 12wks. | Dose-dep increase seminif. Tubule degeneration & decreased DSP. 1 mo recovery, DSP recovered at lowest dose. |
| Reference: Pinkerton et al. (2004, 087465) Species: Rat Gender: Female (pregnant), Offspring- NR Strain: SD Age: 10d (pups), Pregnant females- 10-14d of gestation Weight: NR | PM (Fe and soot from combustion of acetylene and ethylene in a laminar diffusion flame system) Particle Size: Median diameter: 72-74nm; size range: 10-50nm | Route: Inhalation Chamber Dose/Concentration: Mean mass concentration: 243 ± 34 $\mu\text{g}/\text{m}^3$; Average Fe concentration: 96 $\mu\text{g}/\text{m}^3$ Time to Analysis: Exposed 10d postnatal age, 6h/d, 3d (consecutive). Bromodeoxyuridine injected 2h before necropsy. | A significant reduction of cell proliferation occurred only within the proximal alveolar region of exposed animals compared to controls. There were no significant differences between the groups for alveolar formation and separation within the proximal alveolar region |

| Reference: Tsukue et al. (2002, 030593) Species: Mouse Strain: C57/BL Gender: Females, male and female offspring Age: 6wks, 70d post natal (offspring) | Filtered air DE: generated by light-duty, 4-cyl Isuzu diesel engine at 1500 rpm. Particle Size: NR | Route: Whole-body Inhalation Dose/Concentration: 0.3, 1.0 or 3.0 mg DEP/m ³ Time to Analysis: Exposed 12h/d, 7d/wk for 4 mo. Some females sacrificed immediately following exposure. Remainder mated with unexposed males. Parameters measured in offspring at postnatal day 70. | DE-exposed females had Decreased uterine wt at 4 months. Offspring decreased Body weight @ 6 & 8 weeks of age. Decreased rate Of good nest Construction (3 mg/m ³). AGD decreased In males (30 & 70 days old). Organ weight Decreased in Females. Female Crown to rump Length decreased. Relative weights Not taken. |
| Reference: Ueng et al. (2004, 096199) Species: Mouse Gender: Female Strain: Wistar Age: 21d Cell Line: MCF-7 | ME: generated from a Yamaha Cabin motorcycle 2-stroke 50-cc engine and variable venture carburetor Particle Size: NR | Route: Intraperitoneal Instillation. Cell Culture Dose/Concentration: IP: 1, 10, 50 µg/ml Cell Culture: 0.01, 0.1, 1, 10, 50, 100 µg/ml Time to Analysis: IP: 1/d for 3d and sacrificed on 24d. Cell Culture: 3, 24, 30, 48h and 2d. | 10 mg/kg + E2 induced anti-estrogenic uterine effects & Antiestrogenic with in vitro (MCF-7 cells) E2 screen. |
| Reference: Veras et al. (2008, 190493) Species: Mouse Gender: Male, Female Strain: BALB/c Age: 20d, newborns Weight: NR | PM (downtown São Paulo, Brazil near crossroads with high traffic density, 67% PM _{2.5} comprises air pollution) Particle Size: Diameter: 2.5 µm | Route: Open-Top Chamber Dose/Concentration: PM _{2.5} - 27.5 µg/m ³ ; NO ₂ - 101 µg/m ³ ; CO- 1.81 µg/m ³ ; SO ₂ - 7.66ppm Time to Analysis: 20d-old mice maintained in filtered or nonfiltered chamber until 60d-old. Offspring maintained in respective chambers until 21d-old. Offspring mate at 60d-old. Females euthanized 18 th GD. | Fetal weight and maternal blood space volume and surfaces declined in the groups exposed to nonfiltered air. Fetal capillary surfaces were greater in nonfiltered air groups. There was a significant gestational effect on maternal:fetal surface ratios with values declining significantly in groups exposed during pregnancy to nonfiltered air. The total oxygen diffusive conductance of the intervacular barrier increased significantly during pregestational exposure to nonfiltered air. Mass-specific conductance increased during pregestational and gestational periods of exposure to nonfiltered air. |
| Reference: Veras et al. (2009, 190496) Species: Mouse Gender: Male, Female Strain: BALB/c Age: 20d Weight: NR | PM (São Paulo, Brazil; near crossroads with high traffic density) (Al, Ca, Cu, Fe, K, Na, Ni, P, Pb, S, Si, Ti, V, Zn, C) Particle Size: Diameter: 2.5 µm | Route: Open-Top Chamber Dose/Concentration: Mean: Non-filtered- 27.5 µg/m ³ , Filtered- 6.5 µg/m ³ Time to Analysis: 20d-old mice maintained in filtered or non-filtered chamber. Allowed to mate at 60d. 2 generation model. | Ambient air pollution extended the estrus cycle, which reduced the number of cycles. Antral follicles decreased. Mating time increased and fertility and pregnancy indices decreased. The mean post-implantation loss rate increased, which was influenced by both pre- and post-gestational exposure. Fetal weight decreased and was also influenced by pre- and post-gestational exposure, which exhibited a significant interaction. |
| Reference: Watanabe (2005, 087985) Species: Rat Gender: Female (pregnant), Offspring- male Strain: F344/DuCrj Age: 7d of gestation – parturition (females), 96d (offspring) Weight: 240-262g (offspring) | DE (309cc engine, Model NFAD50, Yanmar Diesel Co., Osaka, Japan, 1800rpm, 45% load) (PM, NO ₂) Particle Size: 90% < 0.5 µm | Route: Inhalation Chamber Dose/Concentration: High dose total group: PM- 1.71 µg/m ³ , NO ₂ - 0.79ppm; Low dose total group: PM- 0.17 µg/m ³ , NO ₂ - 0.10ppm Time to Analysis: Pregnant rats exposed gestational day 7 to delivery 6h/d. 5 groups: high dose total DE, high dose PM, NO ₂ filtered, low dose total DE, low dose PM, NO ₂ filtered, clean air control. Offspring sacrificed day 96 after birth. | All groups had significantly less daily sperm production than the control. PM and NO ₂ in DE decreased spermatogenesis but was not significant, however the high dose PM filtered group achieved significance. Pachytene cells, spermatids, and Sertoli cells were lower in all groups compared to the control. |

| Reference: Yauk et al. (2008, 157164) Species: Mouse Strain: C57BL/6 x CBA F1 hybrid Gender: Male Age: 7-9wks | Hepa-Filtered air (PM removed) and ambient air at 2 sites: -2km from two integrated steel mills -1km from major highway on Hamilton Harbor Components: Metals $3.6 \pm 0.7 \mu\text{g}/\text{m}^3$ TSP $9.4 \pm 17 \mu\text{g}/\text{m}^3$ Particle Size: NR | Route: Ambient Air Exposure Dose/Concentration: Ambient air Time to Analysis: Parameters measured 3, 10wks, or 10 + 6wks recovery following exposure. | 10+6 weeks exposure induced increased ESTR mutations in sperm DNA of exposed v filtered. No testicular DNA adducts seen in exposed males. @ 3wks DNA increased adducts seen in lungs of exposed males, not in filtered males. Mutations PM dependent Gas phase independent. |
| Reference: Yokota et al. (2009, 190518) Species: Mouse Gender: Female (pregnant), Male (offspring) Strain: ICR Age: NR Weight: NR | DE (2369-cc diesel engine, Isuzu Motors, Ltd., Tokyo, Japan; 1050rpm, 80% load, commercial light oil) Particle Size: NR | Route: Inhalation Chamber. Pre-natal Exposure Dose/Concentration: DE: 1.0mg/m ³ ; CO: 2.67ppm, NO ₂ : 0.23ppm, SO ₂ : <0.01ppm Time to Analysis: Pregnant mice exposed 8h for 5d from GD 2-17. Mothers and pups kept in clean room. Pups weaned on PND 21 then transported to Tokyo University of Science. 2wk acclimation. Exposed 12h light/dark cycle. Activity monitor with infrared ray sensor measured spontaneous motor activity (SMA), 10min intervals 2d. After behavioral test, mice decapitated. | Prenatal DE exposure decreased SMA in the male offspring. DE decreased locomotor activity during the light phase. Dopamine levels in the striatum and nucleus accumbens did not change, but HVA concentrations decreased in DE-exposed mice. |
| Reference: Yoshida et al. (2006, 156170) Species: Mouse Strain: ICR, C57BL/6J or DDY Gender: Pregnant Females, Male fetuses Age: 14d of gestation (fetuses), 2-13d of gestation (pregnant females) | DE(generated from a 4-cyl., 2300 cc diesel Isuzu engine at 1050 rpm and 80% load). Particle Size: NR | Route: Whole-body Inhalation Dose/Concentration: 0.1 mg DEP/m ³ Time to Analysis: Exposure on 2-13d of gestation. Parameters measured on 14d of gestation. | Responses to exposure showed strain-related variations with ICR as the most sensitive followed by C57 and ddY as the least sensitive. MIS mRNA expression, a factor in male gonadal differentiation, was significantly decreased in the ICR and C57 strains. Ad4BP/SF-1 expression was significantly decreased in the ICR strain only. |
| Reference: Yoshida et al. (2006, 097015) Species: Mouse Strain: ICR Gender: Pregnant females and male offspring Age: 2-16d postcoitum (pregnant females), 28d (male offspring) | DE: generated by 4Jb1-type, light duty 4-cylinder Isuzu diesel engine using standard diesel fuel at 1500 rpm. Particle Size: NR | Route: Whole-body Inhalation Dose/Concentration: 0.3, 1.0 or 3.0 mg DEP/m ³ Time to Analysis: Pregnant females exposed 12h/d, 7d/wk from 2-16d postcoitum. Offspring sacrificed on postnatal day 28. | NOAEL 0.3 mg DEP/m ³ DE exposure induced increased repro gland weight (two higher doses) male mice. mRNA decreases aromatase & 3 μ -hd (3.0 mg DEP/m ³) Sex ratio no change. 2 higher doses induced sig increased repro organ wt. Male pup wt Increased at PND 28. 1.0mg DEP/m ³ pup increased serum T. Serum T positively correlated with DSP, testis wt, steroid enzyme mRNA. |
| Reference: Yoshida et al. 2004 (097760) Species: Mouse Gender: Female (pregnant), Offspring- male Strain: ICR Age: 4, 6wks Weight: NR | DE Particle Size: NR | Route: Inhalation Chamber Dose/Concentration: 6wk-old males, embryos: 0.3, 1.0, 3.0mg DEP/m ³ , Pregnant mice: 0.1, 3.0mg DEP/m ³ Time to Analysis: 6wk-old males: Exposed 12h/d, 6m. 1m clean air exposure. Pregnant mice: Exposed 2-13p.c. 8h/d. Male embryos: Exposed 2-16p.c. Examined at 4wks-old. | 6wk-old males: In the seminiferous tubules, DE dose-dependently caused degenerative and necrotic changes, desquamation of the seminiferous epithelium, and loss of spermatozoa. Spermatogenesis was still inhibited after a 1m clean air exposure. Pregnant mice: Ad4BP/SF-1 and MIS mRNA significantly and dose-dependently decreased in male fetuses exposed to DE. 4wk-old male newborns: Tissue weight of the testis and accessory reproductive glands were significantly greater in DE-exposed mice. Blood testosterone concentration was 8X higher than the control at 1.0mg DEP/m ³ . No significant differences occurred for testosterone synthetase mRNA. |

| Reference: Binkova et al. (2007, 156273) Species: <i>Salmonella</i> (\pm S9 (rat liver)) Cell Line: Calf thymus DNA | PM (Prague, Košice, Sofia, Czech Republic; summer, winter) (organic extracts) Particle Size: Diameter: $< 10 \mu\text{m}$ | Route: Cell Culture Dose/Concentration: 100 μg EOM/mL Time to Analysis: PM collected 24h daily 3m, extracted. 24h incubation BaP, c-PAH, EOM, with or without S9. ^{32}P -Postlabeling 4h. Autoradiography 1-24h. | DNA adducts in EOM treatments were greater with S9 than without. Positive correlations were found between the amount of DNA adducts and the PAH content (notably BaP) in the EOM treatment. |
| Reference: Brits et al. 2007 Species: <i>S. typhimurium</i> Strain: TA98 \pm S9 (Ames); TA104 recN2-4 and TA104pr1 (Vitotox) Cell Line: Human whole blood (Comet, MN assays) | PM (Flanders, Belgium; urban, rural, industrial sites) (organic extracts) Particle Size: Diameter: 10 μm | Route: Cell Culture Dose/Concentration: 2.5, 5, 10, 20 m^3 air equivalents/mL Time to Analysis: Air samples extracted. Ames assay 48h. Vitotox test. Comet assay 24h. MN assay. | Ames: S9 induced mutagenicity of all extracts from all areas in a dose-dependent manner. Without S9, only extracts from the urban and industrial areas were mutagenic at the highest dose. Vitotox: Extracts were toxic at the highest dose. Comet: Significant DNA damage in the extracts was seen and enhanced by S9. MN: A dose-response relationship was seen in the urban extracts for increased micronucleated binuclear cells. |
| Reference: Brown et al. (2005, 095919) Species: <i>S. typhimurium</i> Strain: TA98 Cell Line: Rat hepatoma H4IIE | PM (New Zealand, summer, winter) (extracts) Particle Size: Diameter: 10 μm | Route: Cell Culture Dose/Concentration: 9.7-20.8 $\mu\text{g}/\text{m}^3$ (summer), 21.8-61 $\mu\text{g}/\text{m}^3$ (winter) Time to Analysis: Air samples collected 15d, extracted. Ames test: Bacteria growth 12h, incubated 24h. Hepatoma bioassay: 24h incubation 2x. EROD assay. | Generally, the mutagenic rate was positively correlated to PM ₁₀ , as well as PAH and BaP. PM ₁₀ levels were higher and more mutagenic in winter than summer. |
| Reference: Bunger et al. (2006, 156303) Species: <i>Salmonella typhimurium</i> Strain: TA98, TA 100 | DEP (diesel fuel (DF), low-sulfur diesel fuel (LSDF), rapeseed oil methyl ester (RME), and soybean oil methyl ester (SME)) (SOF-soluble organic fractions) Particle Size: Total particulate matter (no OCC) (gh^{-1}): Mean DF: 4.0 \pm 0.2; 2.8 \pm 0.5; 1.8 \pm 0.0; 3.4 \pm 0.2; 1.2 \pm 0.1 | Route: Cell Culture Dose/Concentration: Log 2 dilutions of extracts: 1.0, 0.5, 0.25, 0.125 Time to Analysis: SOF extracted 12h. Plates incubated 48h. | No OCC: Without oxidation catalytic converter (OCC), DF extract produced the highest number of revertant colonies at all load modes in both TA98 and TA100 \pm S9. RME, SME, and LSDF extracts caused lower or no mutagenic effects, seen especially at partial load modes and idle motion. OCC: With OCC, all extracts reduced the number of revertant colonies in TA98 and TA100 \pm S9 at partial load modes B, C, and D. At load mode A (rated power), there was an increase of the number of revertant colonies in all assays -S9, significant for extracts from RME (TA98, TA100) and SME (TA98). S9 lowered frequency of mutations. At load mode E (idling), number of revertant colonies of DF extracts increased \pm S9. |
| Reference: Bunger et al. (2007, 156305) Species: <i>Salmonella typhimurium</i> Strain: TA98, TA 100 | Diesel engine emissions (DEE)—rapeseed oil (RSO) and rapeseed methyl ester (RME, biodiesel), natural gas derived synthetic fuel (GTL), and diesel fuel (DF) (SOF-soluble organic fractions) Particle Size: NR | Route: Cell Culture Dose/Concentration: Log 2 dilutions of extracts: 1.0, 0.5, 0.25, 0.125 Time to Analysis: SOF extracted 12h. Plates incubated 48h. | Compared to DF, RSO significantly increased mutagenic effects of particle extracts (i.e., revertants) by 9.7-59 in TA98 and by 5.4-22.3 in TA100. (mRSO, RSO with lowered viscosity and fuel preheating in tank, produced highest number of revertant colonies in both strains \pm S9.) RSO fuels condensates had 13.5 times stronger mutagenicity than DF. RME extracts had moderate but significantly higher mutagenic response in TA98 +S9 and TA100 -S9. Effects of GTL did not differ significantly from DF. |
| Reference: de Kok et al. (2005, 086856) Species: <i>S. typhimurium</i> Strain: TA98 (with and without rat liver S9) Cell Line: <i>Salmon testis</i> DNA | TSP (Total suspended particulate, Maastricht, The Netherlands; PM ₁₀ and PM _{2.5} from 6 urban locations with different traffic intensities.) (organic extracts) Particle Size: NR | Route: Cell Culture Dose/Concentration: Mutagenicity assay: 2.5, 9, or 18 m^3 sampled air in 100 μL DMSO; DNA adduct assay: 5 μL DMSO containing PM ₁₀ or TSP from equivalent 50 m^3 sampled air. PM _{2.5} concentration equivalent to 35 m^3 sampled air. Time to Analysis: Mutagenicity assay: Cells incubated 1h with extracts. DNA adduct assay: DNA incubated 4h with extracts. | Overall, the direct mutagenicity and DNA reactivity of PM _{2.5} extracts were higher compared to PM ₁₀ and TSP. S9 generally reduced mutagenic activity in TA98 but increased reactivity to <i>Salmon testis</i> DNA. Total PAH and total carcinogenic PAH levels correlated with the mutagenicity of TSP and the S9-mediated mutagenicity of PM _{2.5} . Neither transition metal composition nor radical generating capacity of PM correlated with mutagenic potential. Total PAH and carcinogenic PAH levels from PM ₁₀ and PM _{2.5} correlated with direct and S9-mediated DNA adducts; for TSP these levels correlated with direct DNA reactivity only. |

| Reference: DeMarini et al (2004, 066329) Species: <i>Salmonella</i> Strain: TA98, TA98NR, TA98/1, 8-DNP6, YG1021, YG1024, TA100 | A-DEP and forklift DEP (SRM 2975) DEP (EOM) Particle Size: Mean Diameter: 0.4 μm | Route: Cell Culture Dose/Concentration: 0, 0.25, 0.5, 1.0, 2.0 EOM $\mu\text{g}/\text{plate}$ Time to Analysis: DEPs sonicated 20min. Centrifuged 10min. Organic material extracted and concentrated. Ames assay. Incubated 3d. | A-DEPs were more mutagenic in both TA98 and TA100 than SRM 2975. There was 22x more PAH-related and 8–45x more nitroarene-related activity. |
| Reference: El Assouli et al. (2007, 186914) Species: <i>S. typhimurium</i> Strain: TA98 (\pm S9) | PM (Jeddah, Saudi Arabia; 11 sites, urban, winter) (organic extracts) Particle Size: Diameter: 10 μm | Route: Cell Culture Dose/Concentration: 2.5, 50, 100 $\mu\text{g}/\text{plate}$; EOM range: 6-40 $\mu\text{g}/\text{m}^3$ Time to Analysis: 24h air samples, extracted. Refluxed 18-24h. GC-MS. Comet assay. 48h incubation. Ames assay. | PAHs varied from 0.83 to 0.18 ng/m^3 . Only 2 locations of heavy petrol driven cars showed strong genotoxic responses. A correlation existed between DNA damage and the amount of pollutants and PAHs. Toxicity and mutagenicity occurred only in the presence of S9. Only 3 of the 11 sites exhibited moderate mutagenic activities. |
| Reference: Endo et al. (2003, 097260) Species: <i>S. typhimurium</i> Strain: YG1024 (\pm S9) | PM (Tokyo, Japan; winter) (organic extracts) Particle Size: Diameter: > 12.1 – 0.06 μm ; Bimodal mass concentration: 1-2 μm | Route: Cell Culture Dose/Concentration: 2.5, 5, 10 μL ; 0.30 – 22.76 $\mu\text{g}/\text{m}^3$ Time to Analysis: Air samples collected, extracted. 90min pre-incubation. 48h incubation. | Mutagenicity tests showed dose-response relationships that were higher without S9 and increased with decreasing size. |
| Reference: Erdinger et al. (2005, 156423) Species: <i>S. typhimurium</i> Strain: TA98, TA100, TA98NR | PM (Baden-Württemberg, Germany; urban, 8 locations, glass fiber filters) (organic extracts) Particle Size: NR | Route: Cell Culture Dose/Concentration: 0.25, 2.5, 5, 12.5, 25 m^3/plate Time to Analysis: Standard Ames test protocol followed. | Extracts were mutagenic in all strains evaluated. No significant difference in response with or without metabolic activation. Activity in TA98NR suggests that the mutagenicity correlates with concentrations of air pollutants such as NOx. |
| Reference: Iba et al. (2006, 156582) Species: <i>S. typhimurium</i> Strain: TA98, TA100 (\pm S9 (rat liver)) | PM (wood smoke (WS) (New Jersey) and cigarette smoke (CS) (Tobacco Research and Health Institute, University of Kentucky)) (organic extracts) Particle Size: 10 μL aliquots of organic extracts | Route: Cell Culture Dose/Concentration: 62.5, 12.5 μg TPM equivalent/plate Time to Analysis: Incubation, shaking 25min. Agar added. 48h incubation. Rat lung explants incubated 18h. 12h incubation with treatments. | WS and CS were equally mutagenic to TA98, but CS was 3-fold more mutagenic to TA100 than WS. CS induced CYP1A1 in the explants, but WS did not. |
| Reference: Liu et al. (2005, 097019) Species: <i>S. typhimurium</i> Strain: YG1024, YG1029 Cell Line: Chinese hamster lung V79 cells | DEP extract (DP), gasoline engine exhaust particulate extract (GP), diesel exhaust SVOC extract (DSVOC), gasoline engine SVOC extract (GSVOC), NIST SRM 1650a Particle Size: Gasoline PM: 0.554mg extract (mg PM) ⁻¹ ; Diesel PM: 0.363mg extract (mg PM) ⁻¹ | Route: Cell Culture Dose/Concentration: 1.48, 4.44, 13.3, 40, 120, 360, 1080 $\mu\text{g}/\text{plate}$ Time to Analysis: 30min preincubation. 48h (YG1029). 66h (YG1024). Overnight preincubation 20h. | Mutations: All samples induced mutations in both strains. The increase was highly significant and dose-dependent. Response with S9 was generally greater than without S9. PM extract was more mutagenic than SVOC extract. DP, GP, and GSVOC: Dose-response was seen for DNA damage and micronuclei induction. GP, GSVOC and SRM 1650a were stronger inducers of micronuclei than DP. |
| Reference: Matsumoto et al. (2007, 187020) Species: <i>S. typhimurium</i> Strain: TA98, TA100 (\pm S9) | APM (airborne particulate matter) APE (airborne particulate extracts) (Hokkaido, Japan; residential) Particle Size: NR | Route: Cell Culture Dose/Concentration: Crude APE: 979mg/m ³ air (CALUX BaP Equivalent (BaPEq)), 21mg/m ³ air (CALUX TCDD Equivalent (TCDD Eq)); Cleaned APE: 7.87mg/m ³ air (CALUX BaPEq), 0.614mg/m ³ air (CALUX TCDD Eq) Time to Analysis: Air samples collected, extracted. Preincubation with <i>S. typhimurium</i> . 3, 24h exposure in CALUX assay. RNA extracted from mice 6d after last application. | Most of the CALUX BaPEq for crude APE was derived from PAH-like compounds, as suggested by the CALUX BaPEq of cleaned APE accounting for 0.80% of CALUX BaPEq for crude APE. CALUX TCDD Eq showed TCDD and similar compounds to have a low contribution. The TA100 strain was more mutagenic to APE, with and without S9. S9 increased mutagenicity in both strains. |

| Reference: Pastorkova et al. (2004, 087431) Species: <i>S. typhimurium</i> Strain: TA98, YG1041 (±S9) | PM (EOM) (Plzeň, Prague, Ústí, Zďár – Czech Republic) Particle Size: Diameter: 10 μ m | Route: Cell Culture Dose/Concentration: TA98 (4 doses): 20-200 μ g/plate, YG1041 (4 doses): 4-20 μ g/plate Time to Analysis: Collected 24h every 18 th day, Oct-Mar, 1999-2003. Extracted. Ames assay. 70h incubation. | Significant dose-response effects in mutagenic potency of EOM occurred. Prague, one of the most polluted cities, had the highest mutagenicity values. Increasing time-trends were observed in the TA98±S9 mutagenicity and PAH concentrations. |
| Reference: Rivedal et al. (2003, 097684) Species: <i>S. typhimurium</i> Strain: TA100, TA98, TA100NR, TA98NR, TA98/1,8-DNP ₆ | DEP (SRM 1850)(organic extracts) (fractionated into PAH, nitro-PAH, dinitro-PAH, aliphatics, polar fraction) Particle Size: NR | Route: Cell Culture Dose/Concentration: Ames: 300, 600 DEP/plate; Gap junction: 100, 200 μ g/mL DEP Time to Analysis: Extracted 16h. Fractionated. Ames assay. Gap junction intracellular communication: exposed 1-6h. Western blot. | TA100 was the most mutagenic without S9 activation. GJIC was dose- and time-dependently inhibited. The polar fraction was the most potent inhibitor. Nitro-PAH and dinitro-PAH were the most responsive fractions in the Ames assay. |
| Reference: Seagrave et al. (2003, 054979) Species: <i>Salmonella</i> Strain: TA98, TA100 | Compressed natural gas (CNG) emissions (heavy-duty vehicles): High emitter (HE), Normal emitter (NE), New technology (NT) Particle Size: NR | Route: Cell Culture Dose/Concentration: PM (mg/mi)- NE- 7.0, NT- 5.0, HE- 406; Recovered PM (mg/mi)- NE-1.26, NT- 0.71, HE- 57.1; Recovered SVOC- NE- 58, NT- 26.4, HE- 227.5 Time to Analysis: Samples collected in filters 7x/d over several days. Recovered PM, recovered SVOC extracts combined. Ames assay. | All three CNG emissions were mutagenic in both strains. Mutagenicity was reduced by S9 in TA100 but not in TA98. Activity ranking in both strains was HE > NE > NT. |
| Reference: Sharma et al. (2007, 156975) Species: <i>S. typhimurium</i> Strain: TA98, YG1041, YG5161 Cell Line: Human A549 lung epithelial cells | PM (airborne, 4 sites: an oven hall and receiving hall in a waste incineration plant; heavy-traffic street; background; Mar-June 2005) Particle Size: Diameter: 2.5 μ m | Route: Cell Culture Dose/Concentration: 0.25mg/ml Time to Analysis: Samples taken over 7-16d. A549 cells incubated 24h. Comet and microsuspension assays performed. | DNA damage: Samples from all four sites induced DNA damage in the comet assay with the street samples more damaging than the oven hall sample. Mutations: Microsuspension assay was used to assess mutagenic activity. No mutagenic activity was observed for any of the non-polar fractions from any sample sites. The moderately polar fractions were all mutagenic, except for the oven hall sample, only when S9 was added. Comparatively, the polar and crude fractions were mutagenic without metabolic activation, suggesting a direct mutagenic effect. |
| Reference: Song et al. (2007, 155306) Species: <i>S. typhimurium</i> Strain: TA98, TA100 Cell Line: Rat fibrocytes L-929 cells | PM (soluble organic fraction (SOF) extracts from diesel engines using fuels blended with ethanol by volume: E0 - base diesel fuel; E5 - 5%; E10 - 10%; E15 - 15%; E20 - 20%) Particle Size: Density (g/cm ³): E0- 0.8379; E5- 0.8349; E10- 0.8324; E15- 0.8301; E20- 0.8279 | Route: Cell Culture Dose/Concentration: Ames Assay: 0.025, 0.05, 0.1mg/plate; Comet Assay: 0.125, 0.25, 0.5, 1.0mg/mL Time to Analysis: Samples extracted 24h. Ames and comet assays performed | All PM extracts induced higher mutational response in TA98 (3- to 5-fold increase over spontaneous) than in TA100 (2-to 3-fold increase). The highest brake specific revertants (BSR) ±S9 in both strains occurred with E20 and lowest BSR was in E5 (except in TA98 –S9). E0 and E20 caused more significant DNA damage (similar in effect) than the other extracts. Damage was dose-dependent but variable with increasing ethanol volume. |
| Reference: Zhang et al. (2007, 157186) Species: <i>S. typhimurium</i> Strain: TA98, TA100 Cell Line: Human lung adenocarcinoma A549 cells | Gasoline engine exhaust (GEE) Methanol engine exhaust (MEE) Particle Size: NR | Route: Cell Culture Dose/Concentration: MTT Assay- 0.05-0.8 GEE or MEE L/ml; MN Assay- 0.025, 0.05, 0.1, 0.2 GEE or MEE L/ml; Comet Assay- 0.025, 0.05, 0.1, 0.2, 0.4 GEE or MEE L/ml; Ames Assay- GEE: 0.625, 1.25, 2.5, 5.0, 10, 20 L/plate; MEE: 0.3125, 0.625, 1.25, 2.5, 5.0, 10, 20 L/plate Time to Analysis: Organic extracts from GEE and MEE. MTT assay- 24h incubation, followed by 2 or 24h incubation, followed by 4h incubation. MN assay- 24h incubation. Comet assay. Ames assay- 72h incubation. | Mutagenicity: GEE was mutagenic in TA98 but not TA100, –S9 at 10 and 20 L/plate and +S9 at ≥1.25 L/plate. Mutagenicity was higher with S9 than without at 0.625-10 L/plate and a dose-response was reported. MEE had no effect in either strain. MN: GEE significantly and dose-dependently induced MN. MEE had no significant effect at any dose. DNA damage: GEE significantly induced DNA damage at all doses compared to controls. MEE had no effect at any dose. |

| Reference: Zhao et al. (2004, 100972) Species: Rat Gender: Male Strain: Sprague-Dawley Age: NR Weight: ~ 200g Cell Line: <i>S. typhimurium</i> YG1024 (± S9) | DEP (SRM 2975) DEPE (SRM 1975) Carbon black (CB) (Elftex-12 furnace black, Cabot, Boston, MA) Particle Size: NR | Route: IT Instilled. Cell Culture. Dose/Concentration: DEP or CB: 35mg/kg body weight; S9: 25, 50, 100, 200 µg/plate; Cytosolic protein: 20, 40, 80, 160 µg/plate; Microsomal protein: 5, 10, 20, 40 µg/plate Time to Analysis: Rats instilled. Sacrificed 1, 3, 7d postexposure. S9, cytosolic, microsomal fractions prepared from lung homogenates. Ames assay: 72h incubation. | DEP and CB-exposed lung S9 time-dependently decreased 2-aminoanthracene (2-AA) mutagenicity. Metryapone and α-naphthoflavone inhibited the S9-activation of 2-AA in DEP and CB exposed rats. Lung S9 increased the mutagenicity of DEPE but not of DEP or CB. Liver S9 reduced DEPE dose-dependently. CYP2B1 and CYP1A1 activated DEPE, with CYP2B1 being more effective. |
| Reference: Zhao et al. (2006, 100996) Species: <i>S. typhimurium</i> Strain: YGL024 (± S9) | DEP (SRM 2975) DEPE (SRM 1975) Aminoguanidine (AG) Particle Size: NR | Route: Cell Culture Dose/Concentration: NR Time to Analysis: Lung S9 obtained from rats used in in vivo experiment. Ames test. Modified microsuspension assay. All assays in duplicate plates. Repeated 3x. | AG significantly lowered 2-aminoanthracene mutagenic activity of DEP or DEPE-exposed lung samples, with DEP being lowered the most. |

| Reference: Abou Chakra et al. (2007, 098819) Species: Human Gender: Male, Female Age: 6-13yrs and Adults Participant Characteristics: Non-smokers Cell Line: HeLa S3 cells | PM (3 French metropolitan cities: Urban PM _{2.5} and PM ₁₀ from "Residential Sector," "Proximity Sector," "Industrial Sector") (organic extracts) Particle Size: Diameter: 2.5, 10 µm | Route: Cell Culture Dose/Concentration: 261 PM _{2.5} ; 76 PM ₁₀ samples Time to Analysis: Cells incubated with 200; µL organic extract and 20 µL aphidicolin for 24h. | Seasonal variation was observed with genotoxic effects being greater in winter. PM _{2.5} was more active than PM ₁₀ extracts. Samples from the "Proximity Sector" (downtown area with heavy traffic) exhibited the strongest genotoxic responses. |
| Reference: Arrieta et al. (2003, 096210) Species: Rat Cell Line: Hepatoma (H4IIE) Species: Mouse Cell Line: Hepatoma H111.1c2 | PM (El Paso, Texas; Juarez, Chihuahua, Mexico; Sunland Park, New Mexico) (organic extracts) Particle Size: Diameter: 10 µm | Route: Cell Culture Dose/Concentration: EROD test: 0.03, 0.17, 0.34, 0.50, 0.68, 4.96, 9.93 extract equivalents (m ³ air); Luciferase: 0.17, 0.51, 1.26, 5.01 extract equivalents (m ³ air) Time to Analysis: Extracts incubated 24h. EROD, luciferase activity, PAH content determined. | EROD activity declined at higher extract amounts, but luciferase activity was not inhibited. Cytotoxicity occurred only at extract equivalents to 0.47 m ³ air. PAH concentration increased with PM mass. |
| Reference: Bao et al. (2007, 097258) Cell Line: Human-hamster hybrid (Au) | DEP (organic extracts) (SRM 2975) Particle Size: NR | Route: Cell Culture Dose/Concentration: 10, 20, 50, 100 µg/mL Time to Analysis: Phagocytosis inhibitors: Exposed 24h with or without cytochalasin B or ammonium chloride. Cytotoxicity: 24, 48h incubation. Mutations: Exposed 24h. 5-7d culture. Incubated additional 7-8d. | The nucleus of DEP-treated cells was condensed and shrunken compared to controls. DEPs accumulated in cells, disrupting the mitochondrial cristae, and were lodged in large cytoplasmic vacuoles. DEP produced minimal toxicity. CD59 locus mutations dose-dependently increased but decreased when simultaneously treated with cytochalasin B or ammonium chloride. |
| Reference: Carvalho-Oliveira et al. (2005, 077898) Species: <i>T. pallida</i> ; <i>A. cepa</i> | PM (Sao Paulo, Brazil; spring, bus strike and non-strike days) (organic extracts) Particle Size: Diameter: 2.5 µm | Route: Cell Culture Dose/Concentration: Strike day: 47.32 µg/m ³ ; Non-strike day: 43.01 µg/m ³ Time to Analysis: Air samples from 2d: bus strike day, bus non-strike day. <i>T. pallida</i> kept in lab 24h. Exposed 8h. 24h recovery. Fixed 24h. <i>A. cepa</i> roots induced 5d. Exposed 30h. Fixed 24h. | Element concentrations, sulfur and BTEX decreased on the strike day. Micronuclei decreased in <i>T. pallida</i> during the strike. Toxicity measured in <i>A. cepa</i> was not significant, but higher on strike days. |

| Reference: Dybdahl et al. (2004, 089013) Species: Human Cell Line: Lung epithelial A549 | DEP (SRM 1650) Particle Size: NR | Route: Cell Culture Dose/Concentration: 10, 50, 100, 500 μg DEP/mL Time to Analysis: DEP suspended, sonicated. A549 cells diluted. Fresh medium added after 24h. After 48h medium removed, DEP added. 2, 5, 24h incubation. | DEP induced dose-dependent increases of IL-1 α , IL-6, IL-8, TNF- α . The cytokines increased 4-18-fold at the highest dose. Cell viability did not decrease. Comet tail length increased at 100 and 500 $\mu\text{g}/\text{mL}$ for 2, 5, 24h. |
| Reference: Gabelova et al. 2006 Species: Human Cell Line: Hepatoma Hep G2 | PM (winter, summer) (organic extracts) Particle Size: Diameter: 10 μm | Route: Cell Culture Dose/Concentration: 5, 10, 20, 50, 100, 150 $\mu\text{g}/\text{mL}$ Time to Analysis: 3m sampling periods, winter, summer. Cells grown 48h. Exposed 2h. Single cell gel electrophoresis or cultivated, harvested, processed 2, 4, 16, 24h. | PM, c-PAHs and genotoxicity were higher in winter air samples than summer. EOM samples generally had significant dose-dependent increases in DNA migration. Repair-specific DNA endonucleases did not increase DNA migration. 8-oxodG was below the steady-state level in EOM samples. |
| Reference: Gabelova et al. 2007 Species: Human Cell Line: Hepatoma Hep G2 | PM (PRG-SM, PRG-LB, Košice, Sofia; winter, summer) (organic extracts) Particle Size: Diameter: 10 μm | Route: Cell Culture Dose/Concentration: 5-150 $\mu\text{g}/\text{mL}$ Time to Analysis: Air samples collected 24h intervals, 3m sampling period. Cells grown 48h. Exposed 2h. 24, 48h preliminary experiments. Single cell gel electrophoresis. | Cell viability significantly decreased in the 24, 48h exposure groups compared to the 2h exposure group. DNA migration significantly dose-dependently increased at most concentrations. In general, oxidative DNA damage did not significantly increase. |
| Reference: Gabelova et al. 2007 Species: Human Cell Line: Hepatoma Hep G2 cell line | PM ₁₀ (Prague (Czech Republic), Košice (Slovak Republic) and Sofia (Bulgaria); urban, winter, summer) (organic extracts) Particle Size: Diameter: 10 μm | Route: Cell Culture Dose/Concentration: 5 to 150 $\mu\text{g}/\text{mL}$ EOM from 50 $\mu\text{g}/\text{mL}$ stock solution Time to Analysis: 24h DNA adduct formation. 2h Comet assay. Oxidative DNA damage measured by Fpg-sensitive sites. | Total DNA adducts ranged from ~60 to 200 adducts per 10 ⁶ nucleotides. Extracts also produced approximately the same levels of strand breaks. Results suggested that the genotoxic potential of ambient air was at least 6-fold greater in the winter compared to summer. No substantial difference was reported for oxidative DNA damage induced by summer vs. winter samples. |
| Reference: Gong et al. (2007, 091155) Species: Human Cell Line: Microvascular endothelial (HMEC) | DEP (aggregates, exhaust 4JB ₁ -type LD, 274 1,4-cylinder Isuzu diesel engine, 10 torque load, cyclone impactor, dilution tunnel constant volume sampler) Particle Size: Diameter: < 1 μm | Route: Cell Culture Dose/Concentration: 5, 15, 25 $\mu\text{g}/\text{mL}$ Time to Analysis: Cells treated with DEP, ox-PAPC (oxidized 1-palmitoyl-2-arachidonoyl-sn-glycero-3-phosphorylcholine), DEP+ox-PAPC. Analytical tests performed. | HO-1 expression was dose-dependent and greatest with the DEP+ox-PAPC treatment. DEP significantly dose-dependently upregulated or downregulated a number of genes and was shown to have a synergistic effect with co-treatment of ox-PAPC. The most varying genes were significantly enriched for EpRE, inflammatory response, UPR, immune response, cell adhesion, lipid metabolism, apoptosis and protein folding genes. |
| Reference: Greenwell et al. (2003, 097478) Species: Rat Cell Line: Epithelial fluid; icosahedral bacteriophage α X174-RF DNA | PM (South Wales, UK) (urban, industrial) Particle Size: Coarse diameter: 10-2.5 μm , Fine diameter: 2.5-0.1 μm | Route: Cell Culture Dose/Concentration: Urban mean: 18.7 \pm 4.7mg/day; Industrial mean: 22.6 \pm 2.5mg/day Time to Analysis: 24h air samples 4-11d. Substrates vortexed 1h, suspended 4h, centrifuged 1h. Oxidation assay. | Industrial PM was more bioreactive than urban PM. Coarse fractions had greater oxidative potential and bioreactivity than fine fractions. |
| Reference: Gu et al. 2005 Species: Hamster Strain: Chinese Cell Line: Lung fibroblast (V79) | DPM (1980 model General Motors 5.7-L V-8 engine) Particle Size: NR | Route: Cell Culture Dose/Concentration: 25, 50, 100, 150 $\mu\text{g}/\text{mL}$; 10 μg DPM in 10 μg in DPPC/mL; 10 μg DPM in 10 μg DMSO/mL Time to Analysis: Chromosomal aberration: 24h incubation. Treated 24h. Incubated again 24h. MN assay: 24h treatment. Gene mutation: 24h treatment. Cells replated. 7d expression times. Staining at 8, 10d. | DPM significantly and dose-dependently increased aberrant cells at 25-100 $\mu\text{g}/\text{mL}$. DPM increased MN formation dose-dependently. Mutant frequencies were not significant and showed no dose-dependent trends. DPM was toxic to cells at the highest concentration. |
| Reference: Gualtieri et al. (2005, 097841) Species: Human Cell Line: Alveolar lung (A549) | TD (Tire debris, generated by rotating new vehicle wheel against a steel brush, significant component of PM ₁₀) (organic extracts) Particle Size: Diameter: 10-80 μm | Route: Cell Culture Dose/Concentration: 50, 60, 75 $\mu\text{g}/\text{mL}$ Time to Analysis: Particles extracted 6h. Cells subcultured every 3-4d. After 24h, TD treatments 24, 48, 72h. | A time- and dose-dependent inhibitory effect on the reduction of MTT was seen. Mortality increased dose-dependently and was significantly greater than the controls. DNA strand breaks increased significantly in a dose-dependent manner. A significant cell cycle block in the G1 phase with a consequent decrease in the cell number in the S and G2/M phases was seen. Exposed cells had a modified morphology. |

| Reference: Gutierrez-Castillo et al. (2006, 089030) Species: Human Cell Line: A549 type II alveolar epithelial cells | PM _{2.5} and PM ₁₀ (4 monitoring stations in Mexico City: (1) downtown high auto traffic, (2) two industrial areas with high levels of auto traffic and low vegetation, (3) medium-traffic residential area) (winter, spring, 4 sampling days in each period) (aqueous and organic extracts) Particle Size: Diameter: 2.5 or 10 μm | Route: Cell Culture Dose/Concentration: 0.05, 0.07, 0.1 m^3/ml equivalents PM _{2.5} ; 0.82, 1.25, 1.63 m^3/ml equivalents PM ₁₀ Time to Analysis: Cells treated 48h with water-soluble or organic-soluble PM extracts. | Higher amounts of water-soluble metals were found in samples collected during winter. Water-soluble extracts increased DNA damage 1.7-fold over the background. Similar results were observed with organic extracts. In general, PM _{2.5} extracts had greater genotoxic potential than PM ₁₀ extracts, and water soluble fractions form both particle sizes were more genotoxic than the corresponding organic extracts. |
| Reference: Izawa H et al. (2007, 190387) Cell Line: NA | DEPE (4JB-1 Isuzu 4-cylinder direct-injection 2740cc diesel engine; 1500rpm, 10kg/m load) Particle Size: NR | Route: Cell Culture Dose/Concentration: DEP: Ah-1 experiment- 111, 55.5, 27.8, 13.9, 6.9, 3.5, 1.7 $\mu\text{g}/\text{mL}$; Foods, polyphenols experiment- 27.8 $\mu\text{g}/\text{mL}$ Time to Analysis: DEPE incubated 2h for dioxin toxicity measurement. Absorbance at 405nm measured. Food, polyphenol inhibitory effects: food extract or polyphenol solution added to cytosol solution, shaken 5min. DEPE added, shaken 5min. 2h incubation. Absorbance at 405nm measured. | The dioxin toxicity equivalent was $6,479 \pm 58\text{ng DEQ/g}$ of DEP. The absorbance showed a sigmoid curve and dose-dependently increased from 6.9 to 27.8 μg DEP/mL. The <i>Ginkgo biloba</i> extract significantly inhibited AhR activation significantly more than the other foods, and was followed by green tea, onions, and garlic. Quercetin and myricetin dose-dependently inhibited AhR activation. Ginkgolides A and B had weak inhibitory effects and resveratrol was the weakest. |
| Reference: Jacobsen et al. (2008, 156597) Species: Mouse Cell Line: FE1-Muta™ lung epithelial cells | DEP (SRM 1650b) Carbon black (CB) (Printex 90) Particle Size: DEP: 18-30nm; CB: 14nm; Agglomerates in suspensions: DEP Peaks- 249nm, CB Peaks- 476nm | Route: Cell Culture Dose/Concentration: 37.5, 75 $\mu\text{g}/\text{mL}$ Time to Analysis: 8 repeated 72h incubations. | Mutagenicity: The 75 $\mu\text{g}/\text{mL}$ dose was significantly increased compared to the 37.5 $\mu\text{g}/\text{mL}$ dose. Linear regression showed a significant increasing trend by increasing exposure. There was no change in the total cell numbers. ROS: ROS production increased in DEP-treated cells after 3h of exposure. CB-treated cells showed a dose-dependent increase. |
| Reference: Karlsson et al. 2004 Species: Human Cell Line: Fibroblasts; calf thymus DNA with human liver microsomes or rat liver S9 | PM (urban dust particles, SRM 1649) (extracted with DCM, acetone, DMSO, water) (Fe 3% w/w, Ti 0.32% w/w, V 0.04% w/w, Mn 0.03% w/w, Cu 0.025% w/w) Particle Size: Mean diameter: < 10 μm | Route: Cell Culture Dose/Concentration: 0.1, 1.0, 10, 100 $\mu\text{g}/\text{cm}^2$ Time to Analysis: Particles extracted. Fibroblasts exposed 24h. Comet assay. Calf thymus incubated 2h with microsomes or S9. ³² P-labelled. | DNA damage increased dose-dependently, and a significant amount of DNA-damaged cells had particle interactions. DNA damage induced by the insoluble particle core significantly increased after each extraction. Native particles were more genotoxic than those extracted with DMSO, DCM and water, but not with acetone or hexane. DMSO extracts had the most adduct-forming PACs, and water extracts had the most oxidizing substances. |
| Reference: Karlsson et al. (2005, 086392) Species: Human Cell Line: Lung epithelial A549 type II | PM (subway station, urban street) Subway particles: O ₂ , Fe (Fe from Fe ₃ O ₄) Street particles: Fe from Fe ₂ O ₃ Particle Size: Diameter: 10 μm | Route: Cell Culture Dose/Concentration: Comet: 5, 10, 20, 40 $\mu\text{g}/\text{cm}^2$; 8-oxodG: 10 $\mu\text{g}/\text{cm}^2$ Time to Analysis: Air sampled 24h daily. Cells grown 24h. Exposed 4h. | Both PM types induced concentration-dependent DNA damage, but subway particles were more potent. Subway particles caused more 8-oxodG formation and oxidation of dG, the latter of which was inhibited by deferoxaminemesylate. Oxidation from subway particles was due to nonsoluble, redox active substances, and soluble substances from street particles. |
| Reference: Karlsson et al. (2006, 156625) Species: Human Cell Line: Lung epithelium A549; monocytes from heparinized whole blood | PM (wood- old, modern boiler; pellets-pellets burner, electrical ignition; tire-road simulator studded, friction tires; Street- busy street, Stockholm; Subway- platform near street) Particle Size: Diameter: 2.5, 10 μm | Route: Cell Culture Dose/Concentration: 40 $\mu\text{g}/\text{cm}^2$ Time to Analysis: Samples collected. Blank filter and Teflon filters used. Cells grown 24h. Comet assay. Monocytes incubated 10d. Macrophages incubated 18h. | All particles tested caused DNA damage, but there was no significant difference between the size fractions. Subway particles were the most genotoxic. The urban street particles were the most potent inducers of the cytokines. On the Teflon filters, PM ₁₀ was somewhat more potent than PM _{2.5} . |
| Reference: Kubátová et al. (2004, 087986) Species: Monkey Cell Line: African green kidney COS-1 (CV-1 cells with origin-defective SV40 mutants); (\pm S9) | PM (DE from diesel bus, wood smoke (WS) from chimney, hardwood smoke) (organic extracts) Particle Size: NR | Route: Cell Culture Dose/Concentration: 25, 50, 100, 200 $\mu\text{g}/\text{mL}$; 50mg of each material used for all experiments Time to Analysis: DE and WS collected. Extracted. 24h cytotoxicity. 2h SOS chromotest. | WS had significantly increased cytotoxicity in fractions of 25-250°C, and DE in nonpolar fractions of 250 and 300°C and polar fractions of 50°C. The cytotoxicity of DE PM nonpolar fractions corresponded to increased concentrations of PAHs. WS was not genotoxic and DE was genotoxic in midpolarity fractions (50-250°C). Genotoxic response was not increased after S9 activation. |

| Reference: Landvik et al. (2007, 096722) Species: Mouse Cell Line: Hepatoma Hepa1c1c7 cells | DEP extracts (DEPE in the paper) Particle Size: NR | Route: Cell Culture Dose/Concentration: 10, 20, 30, 50, 70 $\mu\text{g/mL}$ Time to Analysis: Cells exposed 24h. DNA fragmentation assay. | 50 and 70 $\mu\text{g/mL}$ DEPE did not induce DNA fragmentation but did cleave caspase 3 to a minor extent. |
| Reference: Mehta et al. (2008, 190440) Species: Human Cell Line: Lung adenocarcinoma (A549) | PM (SRM 1949a) Particle Size: Diameter: \square 0.18 μm | Route: Cell Culture Dose/Concentration: 0, 50, 100, 200, 400 $\mu\text{g/mL}$ Time to Analysis: Cell culture and cell viability assay: PM treatment 24h. 10d incubation. Host cell reactivation assay: pGL3-luciferase plasmid UV irradiated 20min. PM treatment 24h. 16h transfection. 24h PM incubation. DNA repair synthesis assay: PM treatment 24h. Proteinase K treatment 30min. supf mutagenesis assay: PM treatment 24h. PM culture 60h. DNA extracted. Overnight incubation of transformed bacteria. | PM reduced colony-forming ability and repair synthesis capacity was proportional to the PM concentration. PM dose-dependently decreased HCR capacity and decreased more than TSP. PM induced cyclobutane dimmers and pyrimidine < 6-4 > pyrimidones mutations in UV-irradiated supf. |
| Reference: Meng et al. 2007 Species: Rat Gender: Male Strain: Wistar Age: NR Weight: Mean: 230g; Range: 200-250g Cell Line: AMs from treated rats | PM (Baotou, Wuwei, China) (normal weather, dust storms, Mar 1-31) (organic extracts, water soluble fractions) Particle Size: 2.5 μm | Route: Cell Culture Dose/Concentration: AM: 0, 33.3, 100, 300 $\mu\text{g/mL}$; Water-soluble: 0, 75, 150, 300 $\mu\text{g/mL}$; Organic extracts: 0, 25, 50, 100 $\mu\text{g/mL}$; Mass concentration normal day: $68.49 \pm 28.83 \mu\text{g/m}^3$; Mass concentration dust storm day: $221.83 \pm 69.89 \mu\text{g/m}^3$ Time to Analysis: Samples collected 24h after 5pm. Extracted. Rats instilled 24h. Killed, lavaged. Cultures 4h. | OC, NH_4^+ , NO_3^- were higher in normal weather PM _{2.5} . SO_4^{2-} , Ca^{2+} were higher in dust storm PM _{2.5} . Fe, Al, Ca, Mg were 5x higher in dust storm PM _{2.5} . Cell viability reduced in a concentration-dependent manner, with normal weather being slightly more cytotoxic. DNA damage was dose-dependently induced, with normal weather and organic extracts showing the greatest damage. |
| Reference: Motta et al. 2004 Species: Hamster Strain: Chinese Cell Line: Epithelial liver, ovary | PM (Catania, Sicily; spring) (organic extracts) Particle Size: NR | Route: Cell Culture Dose/Concentration: 0.60, 1.21, 2.42, 4.85, 9.70, 19.40 $\mu\text{g/mL}$; 0.78, 1.56, 2.12, 6.25, 12.50, 25.00 $\mu\text{g/mL}$ Time to Analysis: 2, 3h air sampling. Extracts 4h. 24h treatment. | The treatment was only slightly cytotoxic at the highest dose. DNA damage and aberrant cells generally increased with dose. No effect was seen in the Chinese hamster ovary cells without metabolic activation. |
| Reference: Oh and Chung (2006, 088296) Cell Line: A549 (Comet), CHO-K1 (CBMN), H4IIE (EROD-microbiassay) | Crude extract (CE) DEP and fractions of CE of DEP (organic extracts: F1 - organic bases, F2 - organic acids, F3 - aliphatic, F4 - aromatic, F5 - slightly polar, F6 - moderately polar, F7 - high polar) Particle Size: Diameter: < 2.5 μm , 87.71%, 2.5-10 μm , 3.87%, > 10 μm , 8.42% | Route: Cell Culture Dose/Concentration: 100 $\mu\text{g/mL}$ Time to Analysis: DEP generated, extracted. Comet assay- 24h incubation, CE, DEP exposed 24h. MN assay- cultured 24h, 4h treatment, growth medium incubation 20h. EROD-microbioassay- 48h. | DNA damage: CE significantly increased the amount of DNA damage in A549 cells with and without SKF-525A, a CYP450 inhibitor, and in CHO-K1 cells. It significantly increased MN formation \pm S9 compared to controls. Organic Extracts: Organic base (F1) and neutral (F3-F7) fractions of CE of DEP significantly induced DNA damage without SKF-525A compared to controls. Adding SKF-525A completely inhibited damage caused by F3, F4, F6 and F7 but kept the effect of F1 similar to that without SKF and only partially inhibited that of F5. F2 did not induce DNA damage with or without SKF. All fractions except F6 induced MN formation \pm S9. |
| Reference: Poma et al. (2006, 096903) Species: Mouse Cell Line: Macrophage RAW 264.7 | PM (L'Aquila, Italy; urban) Carbon black (CB) Particle Size: Diameter: 2.1-0.43 μm | Route: Cell Culture Dose/Concentration: 1, 3, 10 $\mu\text{g/cm}^2$ Time to Analysis: Air samples collected weekly basis Jan-Mar 2004. Cells cultured 48h. Treatment 48h. MN assay: 44h incubation, 28h incubation. | PM and CB dose-dependently reduced cell proliferation and induced micronuclei. PM and CB also reduced cellular metabolism of the macrophages and induced significant amounts of apoptosis. PM produced more micronuclei than equally-weighted CB. |
| Reference: Poma et al. 2006 Species: Mouse Cell Line: RAW 264.7 macrophage | PM (urban, winter) Particle Size: Diameter: 2.5 μm | Route: Cell Culture Dose/Concentration: 2.2, 6.6, 22 $\mu\text{g/mL}$ Time to Analysis: Cells treated with particulates 44h. 28h incubation after cytochalasin B. Micronuclei frequency determined. | Extracts produced a dose-dependent increase in micronuclei. Fine carbon black particles were consistently less genotoxic at similar test concentrations. Results indicate that the chemicals adsorbed onto the particles were the primary contributors to the observed genotoxic effects. |

|--|---|--|--|
| Reference: Roubicek et al. (2007, 156929) Species: Human Cell Line: Lung adenocarcinoma A549 cell line | PM (Mexico City from an industrial area with high-traffic and a medium-traffic residential area) (aqueous or organic extracts) Particle Size: Diameter: 10 μm | Route: Cell Culture Dose/Concentration: 1.25, 1.63, 2.5 m^3/ml equivalents of PM_{10} Time to Analysis: Cells treated 24h followed by 48h incubation with cytochalasin B. Micronuclei frequency determined. | Water and organic extracts induced a significant dose-dependent increase in the micronuclei frequency. After doses of PM from different regions were normalized for mass differences, the genotoxic potency was higher for samples from the industrial area. |
| Reference: Salonen et al. (2004, 187053) Species: Mouse Cell Line: Macrophage RAW 264.7 | PM (Vallila, Finland; busy traffic site; spring, winter) Particle Size: Diameter: < 10 μm | Route: Cell Culture Dose/Concentration: 15, 50, 150, 500, 1000 $\mu\text{g}/\text{mL}$ of RPMI Time to Analysis: Air collected 2-7d periods. Extracted. Exposed 24h. | PAHs decreased from winter to spring. $\text{TNF-}\alpha$ dose-dependently increased and was higher in spring samples. IL-6 generally increased in spring but not in winter. NO dose-dependently increased and was higher in winter. Cell viability generally decreased but there were no consistent potency differences between the samples. Generally, proinflammatory activity, cytotoxicity and IL-6 were associated with the insoluble PM fractions. Polymyxin B inhibited IL-6 and $\text{TNF-}\alpha$. $\cdot\text{OH}$ and 8-hydroxy-2'-deoxyguanosine dose-dependently increased and were higher in the spring and winter, respectively. |
| Reference: Seaton et al. 2005 Species: Human Cell Line: Alveolar epithelial A549 | PM (3 busy London underground (LU) stations and cabs) (LU dust in $\text{PM}_{2.5}$ samples: iron oxide 64-71%, chromium 0.1-0.2%, manganese 0.5-1%, copper < 0.1-0.9%; respirable dust samples: 1-2%) Particle Size: Diameter: < 2.5 μm , 10 μm , Median diameter: 0.4 μm | Route: Cell Culture Dose/Concentration: Stations: 270-480 $\mu\text{g}/\text{m}^3$ $\text{PM}_{2.5}$, 14000-29000 particles/ cm^3 ; Cabs: 130-200 $\mu\text{g}/\text{m}^3$ $\text{PM}_{2.5}$, 17000-23000 particles/ cm^3 ; Assays: 1, 10, 50, 100 $\mu\text{g}/\text{mL}$ Time to Analysis: 3d measurements of LU and cabs. Air collected for lab tests. Exposed 8, 24h. | PM_{10} caused less LDH release, IL-8 stimulation and free radical activity than LU dust particles that contained $\text{PM}_{2.5}$. Chelation had little effect on PM_{10} soluble components. |
| Reference: Sevastyanova et al. (2007, 156969) Species: Human Cell Line: HepG2 cell line, embryonic lung diploid fibroblasts (HEL), or acute monocytic leukemia cells (THP-1) | PM_{10} (Prague, Czech Republic; Košice, Slovak Republic; Sofia, Bulgaria) (urban, summer, winter) (organic extracts) Particle Size: Diameter: 10 μm | Route: Cell Culture Dose/Concentration: 10-100 $\mu\text{g}/\text{mL}$ Time to Analysis: Samples collected 24h daily 3m. HepG2 and THP-1 cells treated for 24h. | DNA adducts were observed in all cell types evaluated. Highest adduct levels were observed in HepG2 cells, followed by HEL and THP-1 cells. A correlation between DNA adduct levels and carcinogenic PAH content was observed in HepG2 cells at 50 $\mu\text{g}/\text{mL}$. |
| Reference: Shi et al. (2003, 088248) Species: Human Cell Line: Epithelial lung A549 | PM (Düsseldorf, Germany, July-Dec.) Particle Size: Fine diameter: < 2.5 μm ; Coarse diameter: 10-2.5 μm | Route: Cell Culture Dose/Concentration: Fine: 0.57-2.49mg; Coarse: 0.66-1.89mg; Concentration: 0.57mg/mL Time to Analysis: Weekly samplings July-Dec 1999. Electron spin response 8-hydroxydeoxyguanosine induction, measurement. | Coarse and fine particles generated $\cdot\text{OH}$, but coarse particles had significantly higher $\cdot\text{OH}$ formation as well as 8-hydroxy-2'-deoxyguanosine formation. 8-hydroxy-2'-deoxyguanosine and $\cdot\text{OH}$ had a significant correlation. |
| Reference: Skarek et al. (2007, 096814) Species: Rat Cell Line: Modified hepatoma H4IIE.luc; SOS: <i>E. coli</i> PQ37 (\pm S9) | PM (urban: Ústí nad Labem, Karviná; background: Cervenohorské sedlo, Košetice – Czech Republic; July) (organic extracts, TSP) GP (gas phase) Particle Size: Diameter: < 2.5 μm | Route: Cell Culture Dose/Concentration: SOS: 8, 4, 2, 1 $\text{m}^3/\text{ml}^{-1}$; Dioxin: TSP + GP: 8, 1.33, 0.22, 0.04 $\text{m}^3/\text{ml}^{-1}$; $\text{PM}_{2.5}$ + GP: 4, 0.66, 0.11, 0.02 $\text{m}^3/\text{ml}^{-1}$ Time to Analysis: 24h samples July 2002. Extracted. SOS chromotest: 22h incubation. Dioxin toxicity test: 24h exposure. | The urban areas had a much greater level of carcinogenic PAHs and overall number of PAHs than the background areas. Significant genotoxic activity was only detected at TSP + GP without S9 from urban areas. $\text{PM}_{2.5}$ + GP had lower dioxin activity at the urban areas, but similar levels of toxicity were seen for both treatments in the background areas. |
| Reference: Song et al. (2007, 155306) Species: <i>S. typhimurium</i> Strain: TA98, TA100 Cell Line: Rat fibrocytes L-929 cells | PM (soluble organic fraction (SOF) extracts from diesel engines using fuels blended with ethanol by volume: E0 - base diesel fuel; E5 - 5%; E10 - 10%; E15 - 15%; E20 - 20%) Particle Size: Density (g/cm^3): E0- 0.8379; E5- 0.8349; E10- 0.8324; E15- 0.8301; E20- 0.8279 | Route: Cell Culture Dose/Concentration: Ames Assay: 0.025, 0.05, 0.1mg/plate; Comet Assay: 0.125, 0.25, 0.5, 1.0mg/mL Time to Analysis: Samples extracted 24h. Ames and comet assays performed | All PM extracts induced higher mutational response in TA98 (3- to 5-fold increase over spontaneous) than in TA100 (2- to 3-fold increase). The highest brake specific revertants (BSR) \pm S9 in both strains occurred with E20 and lowest BSR was in E5 (except in TA98 – S9). E0 and E20 caused more significant DNA damage (similar in effect) than the other extracts. Damage was dose-dependent but variable with increasing ethanol volume. |

| Reference: Ueng et al. (2005, 097054) Species: Human Cell Line: Lung epithelium CL5 (cancerous), bronchial epithelial BEAS-2B (noncancerous), WI-38 normal lung fibroblast | MEP (Yamaha cabin motorcycle 2-strok 50-cc engine) Particle Size: NR | Route: Cell Culture Dose/Concentration: 1, 10, 100, 200 $\mu\text{g/mL}$ Time to Analysis: Exhaust collected, extracted. cDNA microarray analysis. RT-PCR: 2h. ELISA: 12h incubation. Centrifuged 24h post-treatment. Bioactivity: 12h incubation. Centrifuged 24h post-treatment. Medium replaced 48h post-incubation. Fibroblasts determined 96h post-incubation. Time response studies: 3-48h treatment. Concentration response studies: 6h treatment. | Drug metabolism array study: MEP increased CYP1A1, CYP3A7 and UGT2B. Cytokine array study: MEP increased fibroblast growth factor (FGF)-6, FGF-9, IL-1 α , IL-22 and vascular endothelial growth factor (VEGF)-D mRNA. Oncogene, tumor suppressor, estrogen signaling pathway: MEP increased fra-1, c-src, SHC, p21, COX7RP, and decreased p53 and Rb expression. RT-PCR: MEP increased CYP1A1, CYP1B1, IL-6, IL-11, IL-1 α , FGF-6, FGF-9, VEGF-D, fra-1 and p21. Concentration and time responses: Concentration and time-dependent increases occurred for FGF-9, IL-1 α , IL-6, IL-11, but decreased time-dependently after 6h exposure. BEAS-2B Cells: MEP had concentration-dependent increases on CYP1A1 and CYP1B1 but did not affect anything else. Peroxide, MEP + NAC, WI-38 Cells: MEP increased peroxide production. The MEP + NAC treatment reduced MEP-elevated levels of IL-1 α , IL-6, FGF-9, VEGF-D to control levels. Fibroblasts increased in WI-38 cells. |
| Reference: Umbuzeiro et al. (2008, 190491) Species: <i>Salmonella typhimurium</i> Strain: TA98, YG1041 (+/- S9) | PM (urban; São Paulo, Brazil- Cerqueira César street station, Ibirapuera park station) (winter- June 17, 18; average temperature: 16°C) (EOM) Particle Size: NR | Route: Cell Culture Dose/Concentration: Cerqueira César: UPM- 156 $\mu\text{g/m}^3$, EOM- 57.7mg/total UPM; Ibirapuera Park: UPM- 32 $\mu\text{g/m}^3$, EOM- 41.7mg/total UPM; Salmonella assay- 0.5, 1, 5, 10, 50, 100 UPM equiv/plate (μg) Time to Analysis: Tests performed 20d after collection date. Organic extraction 20h. PAH fractionation. Salmonella/microsome assay. | The TSP and EOM were similar for both sites. The PAH fraction had very low mutagenicity for the Cerqueira César sample in the YG1041 strain and no mutagenicity for the Ibirapuera sample. Nitro-PAH and oxy-PAH had similar mutagenetic activities from both samples. S9 decreased mutagenicity in nitro-PAH but was increased in oxy-PAH. DNA adduct levels were dose-dependent and not different between the two sites. |
| Reference: Upadhyay et al. (2003, 097370) Species: Human Cell Line: Alveolar epithelial A549 | PM (Dusseldorf, Germany) (Particles contain carbon (19.70%), hydrogen(1.4%),nitrogen (< .05%), oxygen(14.12%), sulfur (2.09%), ash (63.24%)) (Ionizable metals concentrations (ppm): Co(103), Cu(48),Cr(104),Fe(14,521), Mn(21.3), Ni(1,519),Ti(131), V(2,767) Particle Size: NR | Route: Cell Culture Dose/Concentration: 1, 5, 25, 100 $\mu\text{g/cm}^2$; 10, 25, 50, 100 $\mu\text{g/cm}^2$ Time to Analysis: Air collected. Cells grown 24h. PM treatments 1, 4, 8, 12, 24h. | PM induced dose- and time-dependent reductions in ds-DNA due to the formation of DNA-SB. The soluble component caused higher DNA damage. Apoptosis and DNA fragmentation increased dose-dependently. $\alpha\alpha\text{m}$ decreased dose-dependently in control cells, but not in cells with Bcl-xl overexpression. PM caused activation of caspase 9. Pretreatment with iron chelators or a free radical scavenger reduced PM-induced DNA-SB formation, DNA fragmentation, caspase 9 activation, and weakened $\alpha\alpha\text{m}$ reductions. |
| Reference: Valavanidis et al. (2005, 096432) Cell Line: NR | PM (TSP: high volume pumps, Athens; DEP: 2.0L engine GM Astra; GEP: 1.6L passenger vehicle Ford; Wood smoke soot: domestic fireplace exhaust chimney; PM ₁₀ : high volume sampling system, Athens; PM _{2.5} : high volume cascade impactor (Anderson) system Particle Size: Diameter: > 10.2 - < 0.41 μm | Route: Incubation Dose/Concentration: 20, 40mg/5mL Time to Analysis: PM collected 30min-1h or 24h basis. Incubated with H ₂ O ₂ and 2'-deoxyguanosine (dG). Stored 3-7d at -20°C. Fenton reaction. EPR analysis. | PM generated $\cdot\text{OH}$ by a Fenton reaction, which is increased by the addition of EDTA but inhibited by deferoxamine. PM dose-dependently induced dG hydroxylation and 8-hydroxy-2'-deoxyguanosine formation. Transition metals Ni, V, Co, Cr that are capable of redox cycling electron producing ROS were found in the PM samples. |
| Reference: Xu and Zhang (2004, 097231) Species: Human Cell Line: Lung epithelial A549 | PM (Taiyuan, Beijing; Nov-Feb) (Taiyuan: coal-fume pollution; Beijing: coal-fume and vehicle exhaust) Particle Size: Diameter: 2.5 μm | Route: Cell Culture Dose/Concentration: 5, 50, 200 $\mu\text{g/mL}$ Time to Analysis: Air samples collected. Cells incubated 12-24h. Comet assay. | Taiyuan had a significantly higher daily PM _{2.5} average than Beijing. It was shown that the smaller the particulate diameter, the higher the concentration of BaP and Pb. A dose- and time-response relationship was seen in DNA fragmentation. |

| Reference: Abou Chakra et al. (2007, 098819) Species: Human Gender: Male, Female Age: 6-13yrs and Adults Participant Characteristics: Non-smokers Cell Line: HeLa S3 cells | PM (3 French metropolitan cities: Urban PM _{2.5} and PM ₁₀ from "Residential Sector," "Proximity Sector," "Industrial Sector") (organic extracts) Particle Size: Diameter: 2.5, 10 μm | Route: Cell Culture Dose/Concentration: 261 PM _{2.5} ; 76 PM ₁₀ samples Time to Analysis: Cells incubated with 200; μL organic extract and 20 μL aphidicoline for 24h. | Seasonal variation was observed with genotoxic effects being greater in winter. PM _{2.5} was more active than PM ₁₀ extracts. Samples from the "Proximity Sector" (downtown area with heavy traffic) exhibited the strongest genotoxic responses. |
| Reference: Arrieta et al. (2003, 096210) Species: Rat Cell Line: Hepatoma (H4IIE) Species: Mouse Cell Line: Hepatoma H111.1c2 | PM (El Paso, Texas; Juarez, Chihuahua, Mexico; Sunland Park, New Mexico) (organic extracts) Particle Size: Diameter: 10 μm | Route: Cell Culture Dose/Concentration: EROD test: 0.03, 0.17, 0.34, 0.50, 0.68, 4.96, 9.93 extract equivalents (m^3 air); Luciferase: 0.17, 0.51, 1.26, 5.01 extract equivalents (m^3 air) Time to Analysis: Extracts incubated 24h. EROD, luciferase activity, PAH content determined. | EROD activity declined at higher extract amounts, but luciferase activity was not inhibited. Cytotoxicity occurred only at extract equivalents to 0.47 m^3 air. PAH concentration increased with PM mass. |
| Reference: Bao et al. (2007, 097258) Cell Line: Human-hamster hybrid (A ₁) | DEP (organic extracts) (SRM 2975) Particle Size: NR | Route: Cell Culture Dose/Concentration: 10, 20, 50, 100 $\mu\text{g}/\text{mL}$ Time to Analysis: Phagocytosis inhibitors: Exposed 24h with or without cytochalasin B or ammonium chloride. Cytotoxicity: 24, 48h incubation. Mutations: Exposed 24h. 5-7d culture. Incubated additional 7-8d. | The nucleus of DEP-treated cells was condensed and shrunken compared to controls. DEPs accumulated in cells, disrupting the mitochondrial cristae, and were lodged in large cytoplasmic vacuoles. DEP produced minimal toxicity. CD59 locus mutations dose-dependently increased but decreased when simultaneously treated with cytochalasin B or ammonium chloride. |
| Reference: Carvalho-Oliveira et al. (2005, 077898) Species: <i>T. pallida</i> ; <i>A. cepa</i> | PM (Sao Paulo, Brazil; spring, bus strike and non-strike days) (organic extracts) Particle Size: Diameter: 2.5 μm | Route: Cell Culture Dose/Concentration: Strike day: 47.32 $\mu\text{g}/\text{m}^3$; Non-strike day: 43.01 $\mu\text{g}/\text{m}^3$ Time to Analysis: Air samples from 2d: bus strike day, bus non-strike day. <i>T. pallida</i> kept in lab 24h. Exposed 8h. 24h recovery. Fixed 24h. <i>A. cepa</i> roots induced 5d. Exposed 30h. Fixed 24h. | Element concentrations, sulfur and BTEX decreased on the strike day. Micronuclei decreased in <i>T. pallida</i> during the strike. Toxicity measured in <i>A. cepa</i> was not significant, but higher on strike days. |
| Reference: Dybdahl et al. (2004, 089013) Species: Human Cell Line: Lung epithelial A549 | DEP (SRM 1650) Particle Size: NR | Route: Cell Culture Dose/Concentration: 10, 50, 100, 500 μg DEP/mL Time to Analysis: DEP suspended, sonicated. A549 cells diluted. Fresh medium added after 24h. After 48h medium removed, DEP added. 2, 5, 24h incubation. | DEP induced dose-dependent increases of IL-1 α , IL-6, IL-8, TNF- α . The cytokines increased 4-18-fold at the highest dose. Cell viability did not decrease. Comet tail length increased at 100 and 500 $\mu\text{g}/\text{mL}$ for 2, 5, 24h. |
| Reference: Gabelova et al. 2006 Species: Human Cell Line: Hepatoma Hep G2 | PM (winter, summer) (organic extracts) Particle Size: Diameter: 10 μm | Route: Cell Culture Dose/Concentration: 5, 10, 20, 50, 100, 150 $\mu\text{g}/\text{mL}$ Time to Analysis: 3m sampling periods, winter, summer. Cells grown 48h. Exposed 2h. Single cell gel electrophoresis or cultivated, harvested, processed 2, 4, 16, 24h. | PM, c-PAHs and genotoxicity were higher in winter air samples than summer. EOM samples generally had significant dose-dependent increases in DNA migration. Repair-specific DNA endonucleases did not increase DNA migration. 8-oxodG was below the steady-state level in EOM samples. |
| Reference: Gabelova et al. 2007 Species: Human Cell Line: Hepatoma Hep G2 | PM (PRG-SM, PRG-LB, Košice, Sofia; winter, summer) (organic extracts) Particle Size: Diameter: 10 μm | Route: Cell Culture Dose/Concentration: 5-150 $\mu\text{g}/\text{mL}$ Time to Analysis: Air samples collected 24h intervals, 3m sampling period. Cells grown 48h. Exposed 2h. 24, 48h preliminary experiments. Single cell gel electrophoresis. | Cell viability significantly decreased in the 24, 48h exposure groups compared to the 2h exposure group. DNA migration significantly dose-dependently increased at most concentrations. In general, oxidative DNA damage did not significantly increase. |

|---|--|--|--|
| Reference: Gabelova et al. 2007 Species: Human Cell Line: Hepatoma Hep G2 cell line | PM ₁₀ (Prague (Czech Republic), Košice (Slovak Republic) and Sofia (Bulgaria); urban, winter, summer) (organic extracts) Particle Size: Diameter: 10 µm | Route: Cell Culture Dose/Concentration: 5 to 150 µg/ml EOM from 50 µg/ml stock solution Time to Analysis: 24h DNA adduct formation. 2h Comet assay. Oxidative DNA damage measured by Fpg-sensitive sites. | Total DNA adducts ranged from ~ 60 to 200 adducts per 10 ⁸ nucleotides. Extracts also produced approximately the same levels of strand breaks. Results suggested that the genotoxic potential of ambient air was at least 6-fold greater in the winter compared to summer. No substantial difference was reported for oxidative DNA damage induced by summer vs. winter samples. |
| Reference: Gong et al. (2007, 091155) Species: Human Cell Line: Microvascular endothelial (HMEC) | DEP (aggregates, exhaust 4JB1-type LD, 274 1.4-cylinder Isuzu diesel engine, 10 torque load, cyclone impactor, dilution tunnel constant volume sampler) Particle Size: Diameter: < 1 µm | Route: Cell Culture Dose/Concentration: 5, 15, 25 µg/mL Time to Analysis: Cells treated with DEP, ox-PAPC (oxidized 1-palmitoyl-2-arachidonyl-sn-glycero-3-phosphorylcholine), DEP + ox-PAPC. Analytical tests performed. | HO-1 expression was dose-dependent and greatest with the DEP + ox-PAPC treatment. DEP significantly dose-dependently upregulated or downregulated a number of genes and was shown to have a synergistic effect with co-treatment of ox-PAPC. The most varying genes were significantly enriched for EpRE, inflammatory response, UPR, immune response, cell adhesion, lipid metabolism, apoptosis and protein folding genes. |
| Reference: Greenwell et al. (2003, 097478) Species: Rat Cell Line: Epithelial fluid; icosahedral bacteriophage φX174-RF DNA | PM (South Wales, UK) (urban, industrial) Particle Size: Coarse diameter: 10-2.5 µm, Fine diameter: 2.5-0.1 µm | Route: Cell Culture Dose/Concentration: Urban mean: 18.7 ± 4.7mg/day; Industrial mean: 22.6 ± 2.5mg/day Time to Analysis: 24h air samples 4-11d. Substrates vortexed 1h, suspended 4h, centrifuged 1h. Oxidation assay. | Industrial PM was more bioreactive than urban PM. Coarse fractions had greater oxidative potential and bioreactivity than fine fractions. |
| Reference: Gu et al. 2005 Species: Hamster Strain: Chinese Cell Line: Lung fibroblast (V79) | DPM (1980 model General Motors 5.7-L V-8 engine) Particle Size: NR | Route: Cell Culture Dose/Concentration: 25, 50, 100, 150 µg/mL; 10 µg DPM in 10 µg in DPPC/mL; 10 µg DPM in 10 µg DMSO/mL Time to Analysis: Chromosomal aberration: 24h incubation. Treated 24h. Incubated again 24h. MN assay: 24h treatment. Gene mutation: 24h treatment. Cells replated. 7d expression times. Staining at 8, 10d. | DPM significantly and dose-dependently increased aberrant cells at 25-100 µg/mL. DPM increased MN formation dose-dependently. Mutant frequencies were not significant and showed no dose-dependent trends. DPM was toxic to cells at the highest concentration. |
| Reference: Gualtieri et al. (2005, 097841) Species: Human Cell Line: Alveolar lung (A549) | TD (Tire debris, generated by rotating new vehicle wheel against a steel brush, significant component of PM ₁₀) (organic extracts) Particle Size: Diameter: 10-80 µm | Route: Cell Culture Dose/Concentration: 50, 60, 75 µg/mL Time to Analysis: Particles extracted 6h. Cells subcultured every 3-4d. After 24h, TD treatments 24, 48, 72h. | A time- and dose-dependent inhibitory effect on the reduction of MTT was seen. Mortality increased dose-dependently and was significantly greater than the controls. DNA strand breaks increased significantly in a dose-dependent manner. A significant cell cycle block in the G1 phase with a consequent decrease in the cell number in the S and G2/M phases was seen. Exposed cells had a modified morphology. |
| Reference: Gutierrez-Castillo et al. (2006, 089030) Species: Human Cell Line: A549 type II alveolar epithelial cells | PM _{2.5} and PM ₁₀ (4 monitoring stations in Mexico City: (1) downtown high auto traffic, (2) two industrial areas with high levels of auto traffic and low vegetation, (3) medium-traffic residential area) (winter, spring, 4 sampling days in each period) (aqueous and organic extracts) Particle Size: Diameter: 2.5 or 10 µm | Route: Cell Culture Dose/Concentration: 0.05, 0.07, 0.1m ³ /ml equivalents PM _{2.5} ; 0.82, 1.25, 1.63m ³ /ml equivalents PM ₁₀ Time to Analysis: Cells treated 48h with water-soluble or organic-soluble PM extracts. | Higher amounts of water-soluble metals were found in samples collected during winter. Water-soluble extracts increased DNA damage 1.7-fold over the background. Similar results were observed with organic extracts. In general, PM _{2.5} extracts had greater genotoxic potential than PM ₁₀ extracts, and water soluble fractions from both particle sizes were more genotoxic than the corresponding organic extracts. |
| Reference: Izawa H et al. (2007, 190387) Cell Line: NA | DEPE (4JB-1 Isuzu 4-cylinder direct-injection 2740cc diesel engine; 1500rpm, 10kg/m load) Particle Size: NR | Route: Cell Culture Dose/Concentration: DEP: Ah-1 experiment- 111, 55.5, 27.8, 13.9, 6.9, 3.5, 1.7 µg/mL; Foods, polyphenols experiment- 27.8 µg/mL Time to Analysis: DEPE incubated 2h for dioxin toxicity measurement. Absorbance at 405nm measured. Food, polyphenol inhibitory effects: food extract or polyphenol solution added to cytosol solution, shaken 5min. DEPE added, shaken 5min. 2h incubation. Absorbance at 405nm measured. | The dioxin toxicity equivalent was 6,479 ± 58ng DEQ/g of DEP. The absorbance showed a sigmoid curve and dose-dependently increased from 6.9 to 27.8 µg DEP/mL. The <i>Ginkgo biloba</i> extract significantly inhibited AhR activation significantly more than the other foods, and was followed by green tea, onions, and garlic. Quercetin and myricetin dose-dependently inhibited AhR activation. Ginkgolides A and B had weak inhibitory effects and resveratrol was the weakest. |

|---|---|---|--|
| Reference: Jacobsen et al. (2008, 156597) Species: Mouse Cell Line: FE1-Muta™ lung epithelial cells | DEP (SRM 1650b) Carbon black (CB) (Printex 90) Particle Size: DEP: 18-30nm; CB: 14nm; Agglomerates in suspensions: DEP Peaks- 249nm, CB Peaks- 476nm | Route: Cell Culture Dose/Concentration: 37.5, 75 µg/mL Time to Analysis: 8 repeated 72h incubations. | Mutagenicity: The 75 µg/mL dose was significantly increased compared to the 37.5 µg/mL dose. Linear regression showed a significant increasing trend by increasing exposure. There was no change in the total cell numbers. ROS: ROS production increased in DEP-treated cells after 3h of exposure. CB-treated cells showed a dose-dependent increase. |
| Reference: Karlsson et al. 2004 Species: Human Cell Line: Fibroblasts; calf thymus DNA with human liver microsomes or rat liver S9 | PM (urban dust particles, SRM 1649) (extracted with DCM, acetone, DMSO, water) (Fe 3% w/w, Ti 0.32% w/w, V 0.04% w/w, Mn 0.03% w/w, Cu 0.025% w/w) Particle Size: Mean diameter: < 10 µm | Route: Cell Culture Dose/Concentration: 0.1, 1.0, 10, 100 µg/cm ² Time to Analysis: Particles extracted. Fibroblasts exposed 24h. Comet assay. Calf thymus incubated 2h with microsomes or S9. ³² P-labelled. | DNA damage increased dose-dependently, and a significant amount of DNA-damaged cells had particle interactions. DNA damage induced by the insoluble particle core significantly increased after each extraction. Native particles were more genotoxic than those extracted with DMSO, DCM and water, but not with acetone or hexane. DMSO extracts had the most adduct-forming PACs, and water extracts had the most oxidizing substances. |
| Reference: Karlsson et al. (2005, 086392) Species: Human Cell Line: Lung epithelial A549 type II | PM (subway station, urban street) Subway particles: O ₂ , Fe (Fe from Fe ₃ O ₄) Street particles: Fe from Fe ₂ O ₃ Particle Size: Diameter: 10 µm | Route: Cell Culture Dose/Concentration: Comet: 5, 10, 20, 40 µg/cm ² ; 8-oxodG: 10 µg/cm ² Time to Analysis: Air sampled 24h daily. Cells grown 24h. Exposed 4h. | Both PM types induced concentration-dependent DNA damage, but subway particles were more potent. Subway particles caused more 8-oxodG formation and oxidation of dG, the latter of which was inhibited by deferoxaminemesylate. Oxidation from subway particles was due to nonsoluble, redox active substances, and soluble substances from street particles. |
| Reference: Karlsson et al. (2006, 156625) Species: Human Cell Line: Lung epithelium A549; monocytes from heparinized whole blood | PM (wood- old, modern boiler; pellets- pellets burner, electrical ignition; tire- road simulator studded, friction tires; Street- busy street, Stockholm; Subway- platform near street) Particle Size: Diameter: 2.5, 10 µm | Route: Cell Culture Dose/Concentration: 40 µg/cm ² Time to Analysis: Samples collected. Blank filter and Teflon filters used. Cells grown 24h. Comet assay. Monocytes incubated 10d. Macrophages incubated 18h. | All particles tested caused DNA damage, but there was no significant difference between the size fractions. Subway particles were the most genotoxic. The urban street particles were the most potent inducers of the cytokines. On the Teflon filters, PM ₁₀ was somewhat more potent than PM _{2.5} . |
| Reference: Kubátová et al. (2004, 087986) Species: Monkey Cell Line: African green kidney COS-1 (CV-1 cells with origin-defective SV40 mutants); (± S9) | PM (DE from diesel bus, wood smoke (WS) from chimney, hardwood smoke) (organic extracts) Particle Size: NR | Route: Cell Culture Dose/Concentration: 25, 50, 100, 200 µg/mL; 50mg of each material used for all experiments Time to Analysis: DE and WS collected. Extracted. 24h cytotoxicity. 2h SOS chromotest. | WS had significantly increased cytotoxicity in fractions of 25-250°C, and DE in nonpolar fractions of 250 and 300°C and polar fractions of 50°C. The cytotoxicity of DE PM nonpolar fractions corresponded to increased concentrations of PAHs. WS was not genotoxic and DE was genotoxic in midpolarity fractions (50-250°C). Genotoxic response was not increased after S9 activation. |
| Reference: Landvik et al. (2007, 096722) Species: Mouse Cell Line: Hepatoma Hepa1c1c7 cells | DEP extracts (DEPE in the paper) Particle Size: NR | Route: Cell Culture Dose/Concentration: 10, 20, 30, 50, 70 µg/mL Time to Analysis: Cells exposed 24h. DNA fragmentation assay. | 50 and 70 µg/mL DEPE did not induce DNA fragmentation but did cleave caspase 3 to a minor extent. |
| Reference: Mehta et al. (2008, 190440) Species: Human Cell Line: Lung adenocarcinoma (A549) | PM (SRM 1949a) Particle Size: Diameter: □ 0.18 µm | Route: Cell Culture Dose/Concentration: 0, 50, 100, 200, 400 µg/mL Time to Analysis: Cell culture and cell viability assay: PM treatment 24h. 10d incubation. Host cell reactivation assay: pGL3-luciferase plasmid UV irradiated 20min. PM treatment 24h. 16h transfection. 24h PM incubation. DNA repair synthesis assay: PM treatment 24h. Proteinase K treatment 30min. supf mutagenesis assay: PM treatment 24h. PM culture 60h. DNA extracted. Overnight incubation of transformed bacteria. | PM reduced colony-forming ability and repair synthesis capacity was proportional to the PM concentration. PM dose-dependently decreased HCR capacity and decreased more than TSP. PM induced cyclobutane dimmers and pyrimidine < 6-4 > pyrimidones mutations in UV-irradiated supf. |

| Reference: Meng et al. 2007 Species: Rat Gender: Male Strain: Wistar Age: NR Weight: Mean: 230g; Range: 200-250g Cell Line: AMs from treated rats | PM (Baotou, Wuwei, China) (normal weather, dust storms, Mar 1-31) (organic extracts, water soluble fractions) Particle Size: 2.5 μm | Route: Cell Culture Dose/Concentration: AM: 0, 33.3, 100, 300 $\mu\text{g/mL}$; Water-soluble: 0, 75, 150, 300 $\mu\text{g/mL}$; Organic extracts: 0, 25, 50, 100 $\mu\text{g/mL}$; Mass concentration normal day: $68.49 \pm 28.83 \mu\text{g/m}^3$; Mass concentration dust storm day: $221.83 \pm 69.89 \mu\text{g/m}^3$ Time to Analysis: Samples collected 24h after 5pm. Extracted. Rats instilled 24h. Killed, lavaged. Cultures 4h. | OC, NH_4^+ , NO_3^- were higher in normal weather PM _{2.5} . SO_4^{2-} , Ca^{2+} were higher in dust storm PM _{2.5} . Fe, Al, Ca, Mg were 5x higher in dust storm PM _{2.5} . Cell viability reduced in a concentration-dependent manner, with normal weather being slightly more cytotoxic. DNA damage was dose-dependently induced, with normal weather and organic extracts showing the greatest damage. |
| Reference: Motta et al. 2004 Species: Hamster Strain: Chinese Cell Line: Epithelial liver, ovary | PM (Catania, Sicily; spring) (organic extracts) Particle Size: NR | Route: Cell Culture Dose/Concentration: 0.60, 1.21, 2.42, 4.85, 9.70, 19.40 $\mu\text{g/mL}$; 0.78, 1.56, 2.12, 6.25, 12.50, 25.00 $\mu\text{g/mL}$ Time to Analysis: 2, 3h air sampling. Extracts 4h. 24h treatment. | The treatment was only slightly cytotoxic at the highest dose. DNA damage and aberrant cells generally increased with dose. No effect was seen in the Chinese hamster ovary cells without metabolic activation. |
| Reference: Oh and Chung (2006, 088296) Cell Line: A549 (Comet), CHO-K1 (CBMN), H4IIE (EROD-microbiassay) | Crude extract (CE) DEP and fractions of CE of DEP (organic extracts: F1 - organic bases, F2 - organic acids, F3 - aliphatic, F4 - aromatic, F5 - slightly polar, F6 - moderately polar, F7 - high polar) Particle Size: Diameter: < 2.5 μm , 87.71%, 2.5-10 μm , 3.87%, > 10 μm , 8.42% | Route: Cell Culture Dose/Concentration: 100 $\mu\text{g/mL}$ Time to Analysis: DEP generated, extracted. Comet assay- 24h incubation, CE, DEP exposed 24h. MN assay- cultured 24h, 4h treatment, growth medium incubation 20h. EROD-microbioassay- 48h. | DNA damage: CE significantly increased the amount of DNA damage in A549 cells with and without SKF-525A, a CYP450 inhibitor, and in CHO-K1 cells. It significantly increased MN formation \pm S9 compared to controls. Organic Extracts: Organic base (F1) and neutral (F3-F7) fractions of CE of DEP significantly induced DNA damage without SKF-525A compared to controls. Adding SKF-525A completely inhibited damage caused by F3, F4, F6 and F7 but kept the effect of F1 similar to that without SKF and only partially inhibited that of F5. F2 did not induce DNA damage with or without SKF. All fractions except F6 induced MN formation \pm S9. |
| Reference: Poma et al. (2006, 096903) Species: Mouse Cell Line: Macrophage RAW 264.7 | PM (L'Aquila, Italy; urban) Carbon black (CB) Particle Size: Diameter: 2.1-0.43 μm | Route: Cell Culture Dose/Concentration: 1, 3, 10 $\mu\text{g/cm}^2$ Time to Analysis: Air samples collected weekly basis Jan-Mar 2004. Cells cultured 48h. Treatment 48h. MN assay: 44h incubation, 28h incubation. | PM and CB dose-dependently reduced cell proliferation and induced micronuclei. PM and CB also reduced cellular metabolism of the macrophages and induced significant amounts of apoptosis. PM produced more micronuclei than equally-weighted CB. |
| Reference: Poma et al. 2006 Species: Mouse Cell Line: RAW 264.7 macrophage | PM (urban, winter) Particle Size: Diameter: 2.5 μm | Route: Cell Culture Dose/Concentration: 2.2, 6.6, 22 $\mu\text{g/mL}$ Time to Analysis: Cells treated with particulates 44h. 28h incubation after cytochalasin B. Micronuclei frequency determined. | Extracts produced a dose-dependent increase in micronuclei. Fine carbon black particles were consistently less genotoxic at similar test concentrations. Results indicate that the chemicals adsorbed onto the particles were the primary contributors to the observed genotoxic effects. |
| Reference: Roubicek et al. (2007, 156929) Species: Human Cell Line: Lung adenocarcinoma A549 cell line | PM (Mexico City from an industrial area with high-traffic and a medium-traffic residential area) (aqueous or organic extracts) Particle Size: Diameter: 10 μm | Route: Cell Culture Dose/Concentration: 1.25, 1.63, 2.5 m^3/ml equivalents of PM ₁₀ Time to Analysis: Cells treated 24h followed by 48h incubation with cytochalasin B. Micronuclei frequency determined. | Water and organic extracts induced a significant dose-dependent increase in the micronuclei frequency. After doses of PM from different regions were normalized for mass differences, the genotoxic potency was higher for samples from the industrial area. |
| Reference: Salonen et al. (2004, 187053) Species: Mouse Cell Line: Macrophage RAW 264.7 | PM (Vallila, Finland; busy traffic site; spring, winter) Particle Size: Diameter: < 10 μm | Route: Cell Culture Dose/Concentration: 15, 50, 150, 500, 1000 $\mu\text{g/mL}$ of RPMI Time to Analysis: Air collected 2-7d periods. Extracted. Exposed 24h. | PAHs decreased from winter to spring. TNF- α dose-dependently increased and was higher in spring samples. IL-6 generally increased in spring but not in winter. NO dose-dependently increased and was higher in winter. Cell viability generally decreased but there were no consistent potency differences between the samples. Generally, proinflammatory activity, cytotoxicity and IL-6 were associated with the insoluble PM fractions. Polymyxin B inhibited IL-6 and TNF- α . $\cdot\text{OH}$ and 8-hydroxy-2'-deoxyguanosine dose-dependently increased and were higher in the spring and winter, respectively. |

| Reference: Seaton et al. 2005 Species: Human Cell Line: Alveolar epithelial A549 | PM (3 busy London underground (LU) stations and cabs) (LU dust in PM _{2.5} samples: iron oxide 64-71%, chromium 0.1-0.2%, manganese 0.5-1%, copper < 0.1-0.9%; respirable dust samples: 1-2%) Particle Size: Diameter: < 2.5 μm , 10 μm , Median diameter: 0.4 μm | Route: Cell Culture Dose/Concentration: Stations: 270-480 $\mu\text{g}/\text{m}^3$ PM _{2.5} , 14000-29000 particles/cm ³ ; Cabs: 130-200 $\mu\text{g}/\text{m}^3$ PM _{2.5} , 17000-23000 particles/cm ³ ; Assays: 1, 10, 50, 100 $\mu\text{g}/\text{mL}$ Time to Analysis: 3d measurements of LU and cabs. Air collected for lab tests. Exposed 8, 24h. | PM ₁₀ caused less LDH release, IL-8 stimulation and free radical activity than LU dust particles that contained PM _{2.5} . Chelation had little effect on PM ₁₀ soluble components. |
| Reference: Sevastyanova et al. (2007, 156969) Species: Human Cell Line: HepG2 cell line, embryonic lung diploid fibroblasts (HEL), or acute monocytic leukemia cells (THP-1) | PM ₁₀ (Prague, Czech Republic; Košice; Slovak Republic; Sofia, Bulgaria) (urban, summer, winter) (organic extracts) Particle Size: Diameter: 10 μm | Route: Cell Culture Dose/Concentration: 10-100 $\mu\text{g}/\text{mL}$ Time to Analysis: Samples collected 24h daily 3m. HepG2 and THP-1 cells treated for 24h. | DNA adducts were observed in all cell types evaluated. Highest adduct levels were observed in HepG2 cells, followed by HEL and THP-1 cells. A correlation between DNA adduct levels and carcinogenic PAH content was observed in HepG2 cells at 50 $\mu\text{g}/\text{mL}$. |
| Reference: Shi et al. (2003, 088248) Species: Human Cell Line: Epithelial lung A549 | PM (Düsseldorf, Germany, July-Dec.) Particle Size: Fine diameter: < 2.5 μm ; Coarse diameter: 10-2.5 μm | Route: Cell Culture Dose/Concentration: Fine: 0.57-2.49mg; Coarse: 0.66-1.89mg; Concentration: 0.57mg/mL Time to Analysis: Weekly samplings July-Dec 1999. Electron spin response 8-hydroxydeoxyguanosine induction, measurement. | Coarse and fine particles generated $\cdot\text{OH}$, but coarse particles had significantly higher $\cdot\text{OH}$ formation as well as 8-hydroxy-2'-deoxyguanosine formation. 8-hydroxy-2'-deoxyguanosine and $\cdot\text{OH}$ had a significant correlation. |
| Reference: Skarek et al. (2007, 096814) Species: Rat Cell Line: Modified hepatoma H4IIE.luc; SOS: <i>E. coli</i> PQ37 (\pm S9) | PM (urban: Ústí nad Labem, Karviná; background: Červenohorské sedlo, Košetice – Czech Republic; July) (organic extracts, TSP) GP (gas phase) Particle Size: Diameter: < 2.5 μm | Route: Cell Culture Dose/Concentration: SOS: 8, 4, 2, 1m ³ ml ⁻¹ ; Dioxin: TSP + GP: 8, 1.33, 0.22, 0.04m ³ ml ⁻¹ , PM _{2.5} + GP: 4, 0.66, 0.11, 0.02m ³ ml ⁻¹ Time to Analysis: 24h samples July 2002. Extracted. SOS chromotest: 22h incubation. Dioxin toxicity test: 24h exposure. | The urban areas had a much greater level of carcinogenic PAHs and overall number of PAHs than the background areas. Significant genotoxic activity was only detected at TSP + GP without S9 from urban areas. PM _{2.5} + GP had lower dioxin activity at the urban areas, but similar levels of toxicity were seen for both treatments in the background areas. |
| Reference: Song et al. (2007, 155306) Species: <i>S. typhimurium</i> Strain: TA98, TA100 Cell Line: Rat fibrocytes L-929 cells | PM (soluble organic fraction (SOF) extracts from diesel engines using fuels blended with ethanol by volume: E0 - base diesel fuel; E5 - 5%; E10 - 10%; E15 - 15%; E20 - 20%) Particle Size: Density (g/cm ³): E0- 0.8379; E5- 0.8349; E10- 0.8324; E15- 0.8301; E20- 0.8279 | Route: Cell Culture Dose/Concentration: Ames Assay: 0.025, 0.05, 0.1mg/plate; Comet Assay: 0.125, 0.25, 0.5, 1.0mg/mL Time to Analysis: Samples extracted 24h. Ames and comet assays performed | All PM extracts induced higher mutational response in TA98 (3- to 5-fold increase over spontaneous) than in TA100 (2- to 3-fold increase). The highest brake specific revertants (BSR) \pm S9 in both strains occurred with E20 and lowest BSR was in E5 (except in TA98 – S9). E0 and E20 caused more significant DNA damage (similar in effect) than the other extracts. Damage was dose-dependent but variable with increasing ethanol volume. |
| Reference: Ueng et al. (2005, 097054) Species: Human Cell Line: Lung epithelium CL5 (cancerous), bronchial epithelial BEAS-2B (noncancerous), WI-38 normal lung fibroblast | MEP (Yamaha cabin motorcycle 2-strok 50-cc engine) Particle Size: NR | Route: Cell Culture Dose/Concentration: 1, 10, 100, 200 $\mu\text{g}/\text{mL}$ Time to Analysis: Exhaust collected, extracted. cDNA microarray analysis. RT-PCR: 2h. ELISA: 12h incubation. Centrifuged 24h post-treatment. Bioactivity: 12h incubation. Centrifuged 24h post-treatment. Medium replaced 48h post-incubation. Fibroblasts determined 96h post-incubation. Time response studies: 3-48h treatment. Concentration response studies: 6h treatment. | Drug metabolism array study: MEP increased CYP1A1, CYP3A7 and UGT2B. Cytokine array study: MEP increased fibroblast growth factor (FGF)-6, FGF-9, IL-1 α , IL-22 and vascular endothelial growth factor (VEGF)-D mRNA. Oncogene, tumor suppressor, estrogen signaling pathway: MEP increased fra-1, c-src, SHC, p21, COX7RP, and decreased p53 and Rb expression. RT-PCR: MEP increased CYP1A1, CYP1B1, IL-6, IL-11, IL-1 α , FGF-6, FGF-9, VEGF-D, fra-1 and p21. Concentration and time responses: Concentration and time-dependent increases occurred for FGF-9, IL-1 α , IL-6, IL-11, but decreased time-dependently after 6h exposure. BEAS-2B Cells: MEP had concentration-dependent increases on CYP1A1 and CYP1B1 but did not affect anything else. Peroxide, MEP + NAC, WI-38 Cells: MEP increased peroxide production. The MEP + NAC treatment reduced MEP-elevated levels of IL-1 α , IL-6, FGF-9, VEGF-D to control levels. Fibroblasts increased in WI-38 cells. |

| Reference: Umbuzeiro et al. (2008, 190491) Species: <i>Salmonella typhimurium</i> Strain: TA98, YG1041 (+/- S9) | PM (urban; São Paulo, Brazil- Cerqueira César street station, Ibirapuera park station) (winter- June 17, 18; average temperature: 16°C) (EOM) Particle Size: NR | Route: Cell Culture Dose/Concentration: Cerqueira César: UPM- 156 µg/m ³ , EOM- 57.7mg/total UPM; Ibirapuera Park: UPM- 32 µg/m ³ , EOM- 41.7mg/total UPM; Salmonella assay- 0.5, 1, 5, 10, 50, 100 UPM equiv/plate (µg) Time to Analysis: Tests performed 20d after collection date. Organic extraction 20h. PAH fractionation. Salmonella/microsome assay. | The TSP and EOM were similar for both sites. The PAH fraction had very low mutagenicity for the Cerqueira César sample in the YG1041 strain and no mutagenicity for the Ibirapuera sample. Nitro-PAH and oxy-PAH had similar mutagenetic activities from both samples. S9 decreased mutagenicity in nitro-PAH but was increased in oxy-PAH. DNA adduct levels were dose-dependent and not different between the two sites. |
| Reference: Upadhyay et al. (2003, 097370) Species: Human Cell Line: Alveolar epithelial A549 | PM (Dusseldorf, Germany) (Particles contain carbon (19.70%), hydrogen(1.4%),nitrogen (< .05%), oxygen(14.12%), sulfur (2.09%), ash (63.24%)) (ionizable metals concentrations (ppm): Co(103), Cu(48),Cr(104),Fe(14,521), Mn(21.3), Ni(1,519),Ti(131), V(2,767)) Particle Size: NR | Route: Cell Culture Dose/Concentration: 1, 5, 25, 100 µg/cm ² ; 10, 25, 50, 100 µg/cm ² Time to Analysis: Air collected. Cells grown 24h. PM treatments 1, 4, 8, 12, 24h. | PM induced dose- and time-dependent reductions in ds-DNA due to the formation of DNA-SB. The soluble component caused higher DNA damage. Apoptosis and DNA fragmentation increased dose-dependently. ΔΨ _m decreased dose-dependently in control cells, but not in cells with Bcl-xl overexpression. PM caused activation of caspase 9. Pretreatment with iron chelators or a free radical scavenger reduced PM-induced DNA-SB formation, DNA fragmentation, caspase 9 activation, and weakened ΔΨ _m reductions. |
| Reference: Valavanidis et al. (2005, 096432) Cell Line: NR | PM (TSP: high volume pumps, Athens; DEP: 2.0L engine GM Astra; GEP: 1.6L passenger vehicle Ford; Wood smoke soot: domestic fireplace exhaust chimney; PM ₁₀ : high volume sampling system, Athens; PM _{2.5} : high volume cascade impactor (Anderson) system) Particle Size: Diameter: > 10.2 - < 0.41 µm | Route: Incubation Dose/Concentration: 20, 40mg/5mL Time to Analysis: PM collected 30min- 1h or 24h basis. Incubated with H ₂ O ₂ and 2'-deoxyguanosine (dG). Stored 3-7d at -20°C. Fenton reaction. EPR analysis. | PM generated ·OH by a Fenton reaction, which is increased by the addition of EDTA but inhibited by deferoxamine. PM dose-dependently induced dG hydroxylation and 8-hydroxy-2'-deoxyguanosine formation. Transition metals Ni, V, Co, Cr that are capable of redox cycling electron producing ROS were found in the PM samples. |
| Reference: Xu and Zhang (2004, 097231) Species: Human Cell Line: Lung epithelial A549 | PM (Taiyuan, Beijing; Nov-Feb) (Taiyuan: coal-fume pollution; Beijing: coal-fume and vehicle exhaust) Particle Size: Diameter: 2.5 µm | Route: Cell Culture Dose/Concentration: 5, 50, 200 µg/mL Time to Analysis: Air samples collected. Cells incubated 12-24h. Comet assay. | Taiyuan had a significantly higher daily PM _{2.5} average than Beijing. It was shown that the smaller the particulate diameter, the higher the concentration of BaP and Pb. A dose- and time-response relationship was seen in DNA fragmentation. |

| Reference: Park et al. (2005, 057331) Period of Study: November 2000–October 2003 Location: Greater Boston area, MA | Outcome: Change in HRV (SDNN, HF, LF, LFHFR) Mean age: 72.7 years Study Design: Cross-sectional N: 497 adult males living in the Greater Boston, MA area | Pollutant: PM _{2.5} Averaging Time: 4 h 24 h 48 h Mean (SD): 11.4 (8.0) Range: 6.45–62.9 Copollutant: O ₃ , Particle number count, BC, NO ₂ , SO ₂ , CO | PM Increment: 8 µg/m ³ Percent change (95% CI): 48h mean PM _{2.5} : 20.8% decrease in HF (95% CI: 4.6%, 34.2%) 18.6% increase in LFHFR (4.1%, 35.2%). Notes: Subjects were monitored during a 4-min rest period between 8 a.m. and 1 p.m. Modifying effects of hypertension, IHD, diabetes, and use of cardiac/anti-hypertensive medications also examined. Linear regression analyses. This subject group is from the VA Normative Aging Study. The 4-h averaging period was most strongly associated with HRV indices. The PM effect was robust in models including O ₃ . The HRV change per IQR increase in PM _{2.5} were larger in subjects with hypertension (n = 335) IHD (n = 142), and diabetes (n = 72). In addition, those who did not use calcium-channel blockers had a greater decline in LF associated with each IQR increase in PM _{2.5} than did those who did use calcium channel blockers. IQR increases in 48h mean BC concentration were also associated with adverse changes in HRV, suggesting traffic pollution may be particularly toxic. |
| Reference: Park et al. (2006, 091245) Period of Study: November 2000–December 2004 Location: Greater Boston area, MA | Outcome: Change in HF Study Design: Cross-sectional N: Statistical Analysis: Linear regression models | Pollutant: PM _{2.5} Averaging Time: 48 h Mean (SD): PM _{2.5} : 11.7 (7.8) Sulfates: 3.3 (3.3) BC: 0.92 (0.46) Copollutant: O ₃ | PM Increment: 10 µg/m ³ Percent change (95% CI): Wild-type HFE genotype: 31.7% (95% CI: 10.3, 48.1) Among those with either of the two HFE variants, there was no association between 48h PM _{2.5} and HF (shown in a graph, ~ 10% non-significant increase). Notes: Normative Aging Study. Examining association between PM and HF among those with and without the wild-type HFE genotype. |

| Reference: Pope et al. (2004, 055238) Period of Study: Winter 1999–2000 (in Wasatch Front, UT). Summer 2000 (in Hawthorne, UT). Winter 2000–2001 (in Bountiful, UT and Lindon, UT) Location: Utah: Wasatch Front, Hawthorne, Bountiful, and Lindon | Outcome: Change in autonomic function (measured by changes in HRV), C-reactive protein (CRP), blood cell counts, platelets, and blood viscosity associated with short-term changes in PM _{2.5} Age Groups: Elderly (specific age range not given) Study Design: Panel study N: 88 elderly subjects Statistical Analysis: Linear regression Season: Winter, summer Dose-response Investigated? No | Pollutant: PM _{2.5} (TEOM) Averaging Time: 24 h Mean (SD): 18.9 (13.4) Copollutant: None | PM Increment: 100 µg/m ³ Effect Estimate: Each 100 µg/m ³ increase associated with: -35 (SE = 8) msec decline in SDNN 0.81 (SE 0.17) mg/dL increase in CRP 0.31 (SE 9.34) k/µL increase in platelets 0.07 (SE 0.21) cP increase in blood viscosity Notes: The study observed small but statistically significant adverse associations between daily mean PM _{2.5} and HRV and C-reactive protein (CRP). The authors point out, however, that most of the variability in the temporal deviation of these physiological endpoints was not explained by PM _{2.5} . These observations therefore suggest that PM _{2.5} may be one of multiple factors that influence HRV and CRP. |

(2006, 157177) Period of Study: Nov 2000–Dec 2004 Location: Greater Boston area (Massachusetts) | Outcome: White blood cells (WBC), C-reactive protein (CRP), sediment rate, fibrinogen Age Groups: Mean age (SD) = 73.0 (6.7) Study Design: Cross-sectional N: 710 subjects Statistical Analyses: Linear regression Covariates: Age, BMI, season (also assessed potential for confounding by temperature, RH, barometric pressure, hypertensive or cardiac medications, hypertension, smoking, alcohol, and fasting glucose levels) Dose-response Investigated? No | Pollutant: BC Averaging Time: Hourly (PN, BC, PM _{2.5}) and 24-h (S042–) measurements used to create 48-h, 1-wk, and 4-wk moving averages Mean (SD): 0.77 (0.63) Percentiles: 50th: 0.61 75th: 1.00 90th: 1.51 Monitoring Stations: 2 sites Units: ng/m ³ Copollutant (correlation): PM _{2.5} (r = 0.52) BC PN (r = 0.30) S042– (r = 0.30) | PM Increment: 1 SD increase Effect Estimate (Lower CI, Upper CI): % increase (95%CI) in biomarker per 1 SD increase in pollutant. Fibrinogen 48 h: 0.84 (-0.63, 2.31) 1 wk: 0.60 (-0.95, 2.15) 4 wk: 1.78 (0.19, 3.36) CRP 48 h: 4.51 (-2.03, 11.06) 1 wk: 1.07 (-5.55, 7.68) 4 wk: 5.41 (-1.00, 11.81) Sediment rate 48 h: -4.56 (-25.55, 16.43) 1 wk: 1.98 (-18.15, 22.11) 4 wk: 21.65 (1.48, 41.82) WBC count 48 h: -0.63 (-2.45, 1.19) 1 wk: -0.13 (-1.87, 1.60) 4 wk: -0.55 (-2.36, 1.26) Note: No statistically significant difference was reported for any category of effect modifiers (age, obesity, medications, homozygous for the deletion of GSTM1-null, hypertension) however, results suggested almost all the effect of BC on sediment rate was among the younger group (< 78 yrs) there was a 4-fold difference for the association between BC and CRP in the presence of obesity also evidence for effect modification by obesity of the association between BC and sediment rate there was a suggestive greater effect of BC on CRP among GSTM1-null subjects (9.73% [1.48, 17.98]) vs. GSTM1-present subjects (-2.97% [-14.05, 8.10]) for concentrations 4-wk prior) a stronger effect of BC on sediment rate was seen among non-users of statins (36.01% [13.88, 58.13]) vs users (-12.29% [39.13, 14.55]) |
