| Period of Study: 2005-2006 | fibrinogen, tumor necrosis factor- α (TNF- α) and its soluble receptor-II (TNF-RII) | Averaging Time: 24-h avg preceding the blood draw (lag 0) and cumulative averages up to 5 days preceding the draw | Effect Estimate (Lower CI, Upper CI): |
| Location: Los Angeles, California, air basin | interleukin-6 (IL-6) | Outdoor hourly PM: EC: Mean (SD): 1.61 (0.62) | Note: Nearly all results presented in figures |
| | and its soluble receptor (IL-6sR) | Median: 1.56 | Results: The authors found significant positive associations for CRP, IL-6, sTNF-RII, and sP-selectin with outdoor and/or indoor concentrations of quasi-ultrafine PM α 0.25 μ m in diameter, EC, OC _{pri} , BC, PN, CO, and nitrogen dioxide from the current-day and multiday averages. There were consistent positive but largely nonsignificant coefficients for TNF- α , sVCAM-1, and sICAM-1, but not fibrinogen, IL-6sR, or D-dimer. The authors found inverse associations for erythrocyte Cu, Zn-SOD with these pollutants and other PM size fractions (0.25–2.5 and 2.5–10 μ m). Inverse associations of GPx-1 and MPD with pollutants were largely nonsignificant. Indoor associations were often stronger for estimated indoor EC, OC _{pri} , and PN of outdoor origin than for uncharacterized indoor measurements. There was no evidence for positive associations with SOA. |

| | | | Ischemic heart disease: Annual number of admissions: 346,082 |
| | | | Annual reduction in admissions: 1523 [69, 2976] |
| | | | Heart rhythm disturbances: Annual number of admissions: 169,627 |
| | | | Annual reduction in admissions: 967 [-17, 1951] |
| | | | Heart failure: Annual number of admissions: 246,598 |
| | | | Annual reduction in admissions: 3156 [1923, 4389] |
| | | | COPD: Annual number of admissions: 108,812 |
| | | | Annual reduction in admissions: 990 [196, 1785] |
| | | | Respiratory tract infections: Annual number of admissions: 226,620 |
| | | | Annual reduction in admissions: 2085 [929, 3241] |
| | | | Notes: Figure 2: Point estimates and 95% posterior intervals of the % change in admissions rates per 10 $\mu\text{g}/\text{m}^3$ (national avg relative rates) for single lag (0, 1, and 2 days) and distributed lag models for 0 to 2 days (total) for all outcomes. Summary: Positive significant or marginally significant associations between PM _{2.5} and cerebrovascular disease at Lag 0 |
| | | | peripheral vascular disease at Lags 0 and 2 |
| | | | ischemic heart disease at Lag 2 |
| | | | heart rhythm disturbances at Lag 0 |
| | | | heart failure at Lag 0, Lag 2, and Lags 0 - 2 |
| | | | COPD at Lag 0, Lag 1, and Lags 0-2 |
| | | | and respiratory tract infections at Lag 2 and Lags 0-2. |
| | | | Figure 3: Point estimates and 95% posterior intervals of the % change in admission rates per 10 $\mu\text{g}/\text{m}^3$ (regional relative rates). Summary: For cardiovascular diseases, all estimates in the Midwestern, Northeastern, and Southern regions were positive, while estimates in the other regions (South, West, Central, Northwest) were close to 0. For respiratory disease, there were larger effects in the Central, Southeastern, Southern, and Western regions than in the other regions. |
| | | | Figure 4: Point estimates and 95% posterior intervals of the % change in admission per 10 $\mu\text{g}/\text{m}^3$ (Eastern vs. Western regions): Summary: All estimates for cardiovascular outcomes were |

| Study | Design & Methods | Concentrations [†] | Effect Estimates (95% CI) |
|--|---|---|--|
| | | | positive in the US Eastern region but not in the US Western region. The estimates for respiratory tract infections were larger in the Western region than in the Eastern region. The estimates for CCPD were positive in the both regions. |

| Reference: Allen et al (2008, 156208) Period of Study: 1999-2002 (additional PM composition data collected Dec 2000 and May 2001) Location: Seattle, USA | Outcome: daily changes in exhaled nitric oxide (FENO) and 4 lung function measures, midexpiratory flow (MEF), peak expiratory flow (PEF), forced expiratory volume in one second (FEV ₁), and forced vital capacity (FVC) Age Groups: 6-13 yrs Study Design: Panel study N: 19 children with asthma Statistical Analyses: linear mixed effects model with random intercept to test for within participant associations Covariates: Temperature, relative humidity, BMI, age, and, in the case of FENO, ambient NO measured at a centrally located monitoring site models also included a term for within-participant, within-session effects, and a term for participant between-session effects Effect modification: Decided a priori to include interaction term for PM _{2.5} exposure and inhaled corticosteroids | Pollutant: PM _{2.5} Mean (SD): 11.23 (6.48) Range (Min, Max): 2.76-40.38 25th: 6.38 75th: 14.73 Copollutant (correlation): Ambient LAC* r=0.83 Ambient LG**r=0.84 Personal PM _{2.5} : r=0.34 Personal LAC: r=0.54 Ambient-generated PM _{2.5} : r=0.87 Nonambient-generated PM _{2.5} : r=-0.06 * LAC Light-absorbing carbon ** LG: Leroglucosan (a marker of wood smoke) | Health effect estimates presented in graphic form (Fig 1). Summary from text is as follows: Personal LAC, personal PM _{2.5} , and ambient-generated PM _{2.5} were associated with (p < 0.05) and ambient PM _{2.5} was marginally associated (p=0.09) with increased FENO. Neither of the ambient combustion markers (LAC, LG) nor nonambient-generated PM _{2.5} was associated with FENO changes. All of the ambient concentrations were associated with decrements in PEF and MEF while ambient-generated PM _{2.5} was marginally associated (p < 0.10). Only ambient LG was associated with a decrease in FEV ₁ and there were no associations between exposure metrics and FVC. |

(2005, 086245) Period of Study: 1992-2001 Location: Switzerland (Lugano, Zurich, Bern, Geneva, Anieres, Biel, Langnau, Payerne, & Montana) | Outcome: Respiratory symptoms (chronic cough, bronchitis, cold, dry cough, conjunctivitis, wheeze, sneezing, asthma, & hay fever) Age Groups: 6-15 yrs Study Design: cross-sectional N: 9,591 children Statistical Analyses: Logistic regression models Covariates: age, sex, nationality, parental education, number of siblings, farming status, low birth weight, breast feeding, smoking, family history of asthma, bronchitis and/or atopy, mother who smokes, indoor humidity, mode of cooking & heating, carpeting, pets, removal of carpets/pets for health reasons, completed questionnaire & month, days max temperature < 0°C, mother's belief of association between environmental exposures & respiratory health Dose-response Investigated? Yes Statistical Package: STATA | Pollutant: PM ₁₀ Averaging Time: 12 month avg Mean (SD): NR Range (Min, Max): NR Monitoring Stations: 9 Copollutant (correlation): NR | PM Increment: 10 µg/m ³ <p>"Figure 2 shows that declining levels of PM₁₀ were associated with declining prevalence of chronic cough, bronchitis, common cold, nocturnal dry cough, and conjunctivitis symptoms. For wheezing, sneezing, asthma, and hay fever, no significant association could be seen with declining PM₁₀ levels."</p> <p>"Figure 3 illustrates that, on an aggregate level, across regions the mean change in PM₁₀ levels (r pearson = 0.81, p = 0.008). The strongest decline of adjusted prevalence of nocturnal dry cough was observed in Geneva, Lugano, and Anieres, where the strongest reduction of PM₁₀ had also been achieved."</p> |
| Reference: Burr et al. (2004, 087809) Period of Study: 3 weeks in July and Jan 1997 and 2 weeks in Nov 1996 and April 1997 Location: North Wales, England | Outcome: Self-report of symptoms only for wheeze, cough, phlegm, rhinitis, and itchy eyes. Age Groups: all Study Design: Repeated measures N: 386 persons in congested streets and 425 in the uncongested streets in 1996/1997. Of these, 165 and 283 completed the second phase of the study. | Pollutant: PM ₁₀ Averaging Time: Mean hourly concentrations Mean (SD): SD NR Congested streets – 1996-97 35.2 1998-99 27.2 Uncongested Streets 1996-97 11.6 1998-99 8.2 Monitoring Stations: 1 in congested street and 1 in uncongested | Percent change PM ₁₀ in congested streets: 22.7 Percent change PM ₁₀ in uncongested streets: 28.9 Uncongested street sampling site was 20 m from the congested street sampler. The opening of the by-pass produced a reduction in pollution in the congested streets. The health effects of these changes is likely to be greater for nasal and ocular symptoms than for lower respiratory symptoms. Uncertainty about the causality arises from low response rates and conflicting trends in respiratory and nasal symptoms. |

(2007, 098618) Period of Study: Mar-Aug 2004 Location: Christchurch, New Zealand | Outcome: A clinical study of excretion of 1-hydroxypyrene (1-OHP) as a marker of PAH exposure Age Groups: non-smoking males aged 12-18 yr Study Design: Comparison of 2 high pollution events and 2 low pollution events N: 89 male students in a boarding school Statistical Analyses: Wilcoxon signed rank test for paired observations, Mann-Whitney U test Season: Winter Dose-response Investigated? No | Pollutant: PM ₁₀ Averaging Time: 24 h Mean (SD): Autumn Low Outdoor 19 Indoor NA Winter I Outdoor 43 Indoor 38 Winter II Outdoor 72 Indoor 84 Winter Low Outdoor 12 Indoor 16 Monitoring Stations: One inside the boarding house, and one outside | Urinary 1-OHP were raised after high-pollutions events. Peaks were slightly higher than for US non-smokers of similar ages and slightly lower than for German non-smokers of similar ages. Urinary 1-OHP was slightly higher in asthmatics compared to non-asthmatics. There were no indoor sources of PAHs (wood-burning stoves, tobacco smoke). Diet is another source of PAHs, but all students ate in the boarding house. These results suggest 1-OHP could be used as a biomarker of ambient air pollution. |

| Reference: Janssen et al. (2003, 133555) Period of Study: 4/1997–7/1998 Location: Netherlands–24 schools | Outcome: Symptoms of asthma and allergic disease (asthma, conjunctivitis, hay fever, itchy rash, eczema, phlegm, bronchitis), skin prick test (SPT) reaction to allergens, lung function (forced vital capacity [FVC], forced expiratory volume in one second [FEV ₁], and positive test for fall in FEV ₁ ≥ 15% after inhalation of maximal 23 mL hypertonic saline [BHR = bronchial hyper-responsiveness]) Age Groups: 7-12 years old Study Design: Cohort N: 24 schools (see notes) Statistical Analyses: Multilevel model Covariates: Age, sex, non-Dutch nationality, cooking on gas, current parental smoking, current pet possession, parental education level, number of persons in the household, presence of an unvented water heater in kitchen, questionnaire not filled out by the mother, presence of mold stains in kitchen or living room or bedroom, parental respiratory symptoms, distance of home to motorway, cough or cold at time of lung function measurement, bronchitis or severe cold or flu in 3 weeks preceding measurement, season Dose-response Investigated? No Statistical Package: MLwiN | Pollutant: PM _{2.5} Averaging Time: Annual Mean (SD): 20.5 µg/m ³ (2.2) Percentiles: 25th: 18.6 50th (Median): 20.4 75th: 22.1 Range (Min, Max): 17.3, 24.4 | PM Increment: ‘Difference between the maximum and the minimum of the exposure indicator’ (3.5 µg/m ³) RR Estimate [Lower CI, Upper CI] lag: Current wheeze 1.51 (0.90, 2.53) Asthma ever 1.03 (0.59, 1.82) Current conjunctivitis 2.08 (1.17, 3.71) Hay fever ever 2.28 (1.13, 4.57) Current itchy rash 1.63 (0.91, 2.89) Eczema ever 1.31 (0.94, 1.83) Current phlegm 1.53 (0.74, 3.19) Current bronchitis 1.71 (0.84, 3.50) Elevated total IgE 1.45 (0.74, 2.84) Any allergen (spt reactivity) 1.33 (0.83, 2.11) Indoor allergens (spt reactivity) 1.17 (0.70, 1.94) Outdoor allergens (spt reactivity) 1.90 (1.06, 3.40) FVC < 85% predicted 0.54 (0.29, 1.00) FEV ₁ < 85% predicted 0.88 (0.37, 2.09) BHR 0.93 (0.51, 1.68) Notes: Figure 1 of the article illustrates the association between exposures, including PM _{2.5} , and various respiratory symptoms among children with and without a positive SPT and positive BHR. In general, the association between PM _{2.5} and respiratory symptoms were higher for children with a positive SPT or BHR, except for the outcome of current phlegm. This effect appeared to be the strongest for children with a positive BHR, particularly for current wheeze and current bronchitis. The authors also reported separate analyses for children with SPT reactivity for indoor and outdoor allergens, but did not report any clear differences between the two groups. The authors did report, in the text, that the OR of PM _{2.5} exposure for children sensitized for outdoor allergens was 7.64 for current itchy rash (p < 0.05). |

| Reference: (Burr et al., 2004, 189788) Period of Study: 3 weeks in July and Jan 1997 and 2 weeks in Nov 1996 and April 1997 Location: North Wales, England | Outcome: Self-report of symptoms only for wheeze, cough, phlegm, rhinitis, and itchy eyes. Age Groups: all Study Design: Repeated measures N: 386 persons in congested streets and 425 in the uncongested streets in 1996/1997. Of these, 165 and 283 completed the second phase of the study. | Pollutant: PM _{2.5} Averaging Time: Mean hourly concentrations Mean (SD): Congested Streets 1996-97 21.2 1998-99 16.2 Uncongested Streets 1996-97 6.7 1998-99 4.9 Monitoring Stations: 1 in congested street and 1 in uncongested | % change PM ₁₀ in congested streets: 23.6 % change PM ₁₀ in uncongested streets: 26.6 Uncongested street sampling site was 20 m from the congested street sampler. The opening of the by-pass produced a reduction in pollution in the congested streets. The health effects of these changes are likely to be greater for nasal and ocular symptoms than for lower respiratory symptoms. Uncertainty about the causality arises from low response rates and conflicting trends in respiratory and nasal symptoms. |

| | Study Design: Cohort study | Third trimester: 45.4 (15.5) | First trimester |
| | N: 3901 children | Monitoring Stations: 1 or 3 (See notes) | 20 µg/m ³ : -3.0 (-22.7, 16.7) |
| | Statistical Analyses: Linear mixed-effects | Copollutant (correlation): Entire pregnancy | Second trimester |
| | Logistic regression | PM ₁₀ -O ₃ [10-6]: r = 0.54 | 19 µg/m ³ : -15.7 (-36.1, 4.7) |
| | Covariates: Maternal age, months since last live birth, parity, maternal smoking during pregnancy, SES, marital status at childbirth, gestational diabetes, child's sex, child's race/ethnicity, child's grade in school (4th, 7th, and 10th), Julian day of birth | PM ₁₀ -O ₃ [24 hr]: r = 0.20 | Third trimester |
| | Season: All | PM ₁₀ -NO ₂ : r = 0.55 | 20 µg/m ³ : -21.7 (-42.2 to -1.1) |
| | Dose-response Investigated? Yes | PM ₁₀ -CO: r = 0.41 | Multipollutant model |
| | Statistical Package: SAS | First trimester | (included O ₃ |
| | | PM ₁₀ -O ₃ [10-6]: r = 0.54 | (24 hr) in model |
| | | PM ₁₀ -O ₃ [24 hr]: r = 0.34 | third trimester exposure) |
| | | PM ₁₀ -NO ₂ : r = 0.48 | 20 µg/m ³ : -10.8 (-31.8, 10.2) |
| | | PM ₁₀ -CO: r = 0.29 | Outcome: IUGR (ORs) |
| | | Second trimester | Single-pollutant model |
| | | PM ₁₀ -O ₃ [10-6]: r = 0.50 | Entire pregnancy |
| | | PM ₁₀ -O ₃ [24 hr]: r = 0.27 | 18 µg/m ³ : 1.1 (0.9, 1.3) |
| | | PM ₁₀ -NO ₂ : r = 0.53 | First trimester |
| | | PM ₁₀ -CO: r = 0.35 | 20 µg/m ³ : 1.0 (0.9, 1.2) |
| | | Third trimester | Second trimester |
| | | PM ₁₀ -O ₃ [10-6]: r = 0.52 | 19 µg/m ³ : 1.0 (0.9, 1.2) |
| | | PM ₁₀ -O ₃ [24 hr]: r = 0.31 | Third trimester |
| | | PM ₁₀ -NO ₂ : r = 0.52 | 20 µg/m ³ : 1.1 (0.9, 1.3) |
| | | PM ₁₀ -CO: r = 0.37 | Outcome: LBW |
| | | Notes: Exposure estimates were calculated by spatially interpolated monthly averages which were based off of three monitoring stations located within 50 km of the ZIP code region of maternal birth residences. | Single-pollutant model |
| | | | Entire pregnancy |
| | | | 18 µg/m ³ : 1.3 (0.8, 2.2) |
| | | | First trimester |
| | | | 20 µg/m ³ : 1.0 (0.7, 1.5) |
| | | | Second trimester |
| | | | 19 µg/m ³ : 1.2 (0.8, 1.7) |
| | | | Third trimester |
| | | | 20 µg/m ³ : 1.3 (0.9, 1.9) |
| | | | Notes: Numbers reported for birth weight outcome are the effects on birth weight outcome (the change in birth weight in grams) across the IQR (which vary depending on air pollutant and duration of exposure measurement). |

Annex F. Source Apportionment Studies

Table F-1. Epidemiologic studies of ambient PM sources, factors, or constituents.

| | | | | | | |
|---|---|--------------|---|---|--|--|
| Reference: Andersen et al. (2007, 093201) Location: 1 monitor in Copenhagen, Denmark/ 6 years, but apportionment done for 1.5 year only (2002-2003) Particle Size: PM ₁₀ | Subjects: NR Exposure: NR | n: NR | Number of constituents considered for grouping: 31 | Grouping method: PCA + PMF/CMB hybrid (COPREM) # of groups: 12, but only 6 used in relating to health effects, and CO, NO ₂ | Groups/Factors/ Sources: Road, Vehicle, Salt, Biomass, Oil, Coal, Rock, Lime, NaNO ₃ , NH ₄ NO ₃ , (NH ₄) ₂ SO ₃ , (NH ₄)SO ₄ | PM variables used: Mass contribution of sources |
| Results: Single pollutant models: Biomass, secondary compounds, oil, and crustal significantly associated with CVD HA (4 day moving ave). Biomass and secondary components significantly associated with respiratory HA (5 day moving average). No significant effects for asthma HA in children (6 day moving average). Two pollutant models: Crustal effect for CVD admissions remained robust. Biomass effect for respiratory admissions was highest. Effect of vehicle source remained robust for asthma admissions in children in presence of other PM ₁₀ sources. | | | | | | |
| Reference: Bell et al. (Bell et al., 2009, 191007) Location: PM _{2.5} : 2000-2005 (6 years)/106 US counties/EPA composition data PM ₁₀ : 1987-2000/100 counties/EPA composition data Particle Size: PM ₁₀ , PM _{2.5} | Subjects: NR Exposure: NR | n: NR | Number of constituents considered for grouping: 16 elements + NO ₃ , SO ₄ , EC, OC | Grouping method: NR # of groups: NR | Groups/Factors/ Sources: NR | PM variables used: Every component (16 elements + NO ₃ , SO ₄ , EC, OC) |
| Results: Mortality: Ni significantly increased PM ₁₀ mortality risks. However, effect of Ni was not significant when NY City was removed, in a sensitivity analysis conducted by selectively removing cities from the overall estimate. Hospital Admissions: CVD and respiratory HAs higher in counties with higher EC, Ni, and V PM _{2.5} . In CVD association between PM _{2.5} , RR and V robust to inclusion of EC or V, and V robust to inclusion of EC. | | | | | | |
| Reference: Cakmak et al. (2009, 191995) Location: 1 monitor in Santiago, Chile Particle Size: PM _{2.5} | Subjects: NR Exposure: 1998-2009 (8.3 years) | n: NR | Number of constituents considered for grouping: 16 elements + CO, NO ₂ , SO ₂ , EC, OC | Grouping method: PCA # of groups: 4 | Groups/Factors/ Sources: Vehicle (CO, NO ₂ , EC, OC), Soil (Al, Ca, Fe, Si), Combustion (Cr, Cu, Fe, Mn, Zn), Factor 4 (Br, Cl, Pb) | PM variables used: individual components, then groupings |
| Results: Individual components: EC, OC only stat. sign. risk estimates for total, cardiac, and respiratory mortality for 1 day lag after adjustment for other elements. Groupings: Lag 1. Vehicle factor: Increased total mortality, cardiac mortality, and respiratory mortality. Soil factor: increased cardiac mortality and respiratory mortality (but smaller than vehicle factor RRs). Combustion factor: greatest RR for respiratory mortality, but significant for total and cardiac mortality. Factor 4: increased total, cardiac, and respiratory mortality. Point estimates for Factor 1 significantly different from Factors 3 and 4. Elderly had higher risk estimates for combustion and soil sources. No significant effect modification by gender or season. | | | | | | |

Note: Hyperlinks to the reference citations throughout this document will take you to the NCEA HERO database (Health and Environmental Research Online) at <http://epa.gov/hero>. HERO is a database of scientific literature used by U.S. EPA in the process of developing science assessments such as the Integrated Science Assessments (ISA) and the Integrated Risk Information System (IRIS).

| | | | | | | |
|---|--|------------------------|--|---|---|---|
| Reference: Franklin et al. (2008, 155779) Location: STN/25 communities/2000-2005 (6 years) Particle Size: PM _{2.5} | Subjects: NR Exposure: NR | n: NR | Number of constituents considered for grouping: 15 elements + EC, OC, NO ₃ | Grouping method: NR # of groups: NR | Groups/Factors/ Sources: NR | PM variables used: Every component |
| Results: The PM _{2.5} -mortality association was significantly modified by Al, As, Sulfate, Ni, and Si. When including a combination of species proportions and using backwards elimination Al, sulfate, and Ni remained significant. Al and Ni explained most of the residual heterogeneity. | | | | | | |
| Reference: Gent et al. (2009, 180399) Location: 2 monitors in New Haven, CT/ 3.5 years Particle Size: PM _{2.5} | Subjects: Children with physician diagnosed asthma and symptoms or medication use in previous 12 months, and resided within 30km of New Haven county monitor Exposure: NR | n: 149 children | Number of constituents considered for grouping: 17 elements + EC | Grouping method: PCA # of groups: 6 | Groups/Factors/ Sources: Vehicle (EC, Zn, Pb, Cu, Se), road dust (Si, Fe, Al, Ca, Ba, Ti), sulfur (S, P), biomass burning, (K) oil (V, Ni), sea salt (Na, Cl) In addition, effects of NO ₂ , CO, SO ₂ , and O ₃ were included in the health outcomes model | PM variables used: Groupings and individual elements |
| Results: Overall: Trace elements originating from motor vehicle, road dust, biomass burning, and oil sources associated with symptoms and/or medication use. No associations with S or sea salt. Specific Results: PM _{2.5} mass from motor vehicle or road dust associated with increased odds of respiratory symptoms or inhaler use. Reduced odds of wheeze or inhaler use with same day S. Significant reductions odds of wheeze with biomass burning. Co-pollutant: Positive effects of motor vehicles and road dust on wheeze were robust to the inclusion of gaseous copollutants. However, NO ₂ increases association with wheeze. | | | | | | |
| Reference: Ito et al. (2006, 188554) Location: Washington, DC Particle Size: PM _{2.5} | Subjects: NR Exposure: NR | n: NR | Number of constituents considered for grouping: NR | Grouping method: Comparison of: PMF; (absolute) PCA; UNMIX # of groups: 6-10 Groups/ Factors/ Sources: Different research groups gave different names to sources | Sources for which association with health was analyzed: Soil, traffic, Secondary SO ₄ , NO ₃ (Wash DC only), residual oil (Wash DC only), Wood smoke/ biomass combustion, Sea salt, incinerator (Wash DC only), primary coal (Wash DC only), Cu smelter (Phoenix only) | PM variables used: Mass contribution of sources |
| Results: Overall, PM _{2.5} effects observed at lag 3. Lag structure of association varied across source types, but consistent across investigators for total (non-accidental mortality): soil factor - mostly positive at various lags (not significant); secondary sulfate - strongest association at lag 3; nitrate - mostly negative except at lag 3; residual oil - strongest association at lag 2 (not significant); wood-burning - increasing association as lag increases (not significant); incinerator - significant negative associations at lag 0; primary coal - significant association at lag 3. | | | | | | |
| Reference: Laden et al. (2000, 012102) Location: Monitors in 6 Eastern US cities (Harvard Six Cities) | Subjects: NR Exposure: NR | n: NR | Number of constituents considered for grouping: 15 elements | Grouping method: PCA # of groups: 8 | Groups/ Factors/ Sources: Soil/Crustal (PM fine), Mobile vehicle exhaust (PM fine), Coal (PM fine), Fuel oil; Metals, Salt' Manganese, Residual | PM variables used: Tracers: Si, V, Cl, Pb, Se |

| | | | | | | |
|---|--|-------|---|---|--|---|
| Study) | | | | | | |
| Particle Size: NR | <p>Results: Lag 0-1 average for all results. Over all 6 cities, mobile source factor (using Pb as tracer) had greatest association with daily mortality (3.4%) with 10 $\mu\text{g}/\text{m}^3$ increase. The greatest effects for mortality due to mobile sources were observed in Madison (Portage), Knoxville (Kingston-Harriman), and St. Louis, although the Madison results were not statistically significant. The coal source factor was only significant in Boston (Watertown) - 2.8% increase in mortality and the overall percent increase was also significant (1.1%). Deaths from pneumonia attributable to coal combustion sources was 7.9% (CI 3.1-12.7%) and statistically significant. The crustal factor was not associated with mortality in any city, although this factor was not a significant predictor in the regression model for Boston (Watertown) due to its low contribution to $\text{PM}_{2.5}$ mass. For specific elements included simultaneously, S, Pb, and Ni were significantly associated with overall mortality (3.0, 1.6, 1.5%, respectively). Boston had the greatest percent increase in mortality for S (7.9%), Knoxville for Pb (15.0%), and Steubenville for Ni (8.2%), although the CIs are all quite large.</p> <p>Reanalysis results (Schwartz, 2003): Effects changed slightly. New percent increases in mortality for combined cities are 3.5 and 0.79 for traffic and coal, respectively. The coal factor in Boston decreased to 2.1% increased mortality. A residual oil factor in Boston and Steubenville resulted in at 22.9% increase in daily deaths (but was not significant in the original analysis).</p> | | | | | |
| Reference: Lanki et al. (2006, 088412) Location: Monitors in Helsinki, Finland, Amsterdam, The Netherlands and Erfurt, Germany Particle Size: UF/ $\text{PM}_{2.5}$ | Subjects: NR Exposure: NR | n: NR | Number of constituents considered for grouping: 13 elements | Grouping method: Absolute PCA # of groups: 5 | Groups/ Factors/ Sources: Crustal; long range transported; oil combustion; soil; traffic | PM variables used: Tracers: Si (crustal); S (long-range transport); Ni (oil combustion); Cl (salt); ABS (local traffic). |
| <p>Results: Highest observed effects were for crustal sources and salt at lag 3 (when analyzing sources), but not consistent or significant. In multipollutant models only ABS associated with ST-segment depression, but wide CIs. When examining indicator elements of a source, local traffic found to be the most toxic, but when examined per IQR long-range transport and traffic had similar effects.</p> <p>Results: All had significant associations with mortality. Traffic density and EC had the largest effects.</p> | | | | | | |
| Reference: Lippmann et al. (2006, 091165) Location: U.S. Particle Size: PM_{10} for risk estimates, $\text{PM}_{2.5}$ for speciation data | Subjects: NR Exposure: NR | n: NR | Number of constituents considered for grouping: NR | Grouping method: No grouping was performed # of groups: NR | Groups/ Factors/ Sources: NR | PM variables used: Mass contribution of 16 constituents |
| <p>Results: The strongest predictions of the variation in PM_{10} risk estimates across the 90 NMMAPs MSAs was for Ni and V. Elevated, but nonsignificant increases were associated with EC, Zn, SO_4^{2-}, Cu, Pb, and OC. Al and Si had the lowest values.</p> | | | | | | |
| Reference: Mar et al. (2000, 001760) Location: 1 monitor in Phoenix, AZ Particle Size: NR | Subjects: Elderly only Exposure: NR | n: NR | Number of constituents considered for grouping: 10 elements, OC, EC, CO, NO_2 ; SO_2 | Grouping method: Unspecified type of factor analysis # of groups: 3 or 5 | Groups/ Factors/ Sources: Motor exhaust/road dust, soil, vegetative burning, local SO_2 , regional SO_4 | PM variables used: First used individual constituents: S, Zn, Pb, K, OC, EC, TC (AL + Si + Ca + Fe + Ti), then factor scores |
| <p>Results: Cardiovascular mortality associated with $\text{PM}_{2.5}$ mass on lag 1 and 4 (6 and 4%, respectively). EC and TC associated with CV mortality for lag 1 (RR = 1.05); OC was weakly associated with CV mortality for lags 1 and 3. For total mortality, regional sulfate was positively associated at lag 0, but negatively associated at lag 3. The local SO_2 and the soil factors were negatively associated with total mortality. For CV mortality, secondary sulfate was positively associated at lag 0, motor vehicle at lag 1, and vegetative burning at lag 3.</p> <p>Reanalysis results (Mar, 2003): Similar associations were observed.</p> | | | | | | |
| Reference: Mar et al. (2006, 086143) Location: Phoenix, AZ Particle Size: $\text{PM}_{2.5}$ | Subjects: NR Exposure: NR | n: NR | Number of constituents considered for grouping: NR | Grouping method: Comparison of: PMF (absolute); PCA; UNMIX # of groups: 6-10 Groups/ Factors/ Sources: Different labs gave different names to sources (see Hopke et al, table 2) | Sources for which association with health was analyzed: Soil, Traffic, secondary SO_4 , NO_3 , (Wash DC only), residual oil (Wash DC only), woodsmoke/ biomass combustion, sea salt, incinerator (Wash DC only); primary coal (Wash DC only); Cu smelter (Phoenix only) | PM variables used: Mass contribution of sources |
| <p>Results: Using daily $\text{PM}_{2.5}$ data found the following associations with cardiovascular mortality: Secondary sulfate - greatest effect observed for all sources and at lag 0; traffic - associated at lag 1; copper smelter associated at lag 0; sea salt - had the greatest statistical significance and observed at lag 5; biomass/wood burning - less consistent lag structure but greatest association at lag 3; soil - did not show an association or consistent lag structure. For total (non-accidental) mortality associations were weaker and consistently observed for only: copper smelter - lag 0; sea salt - lag 5.</p> | | | | | | |

| | | | | | | |
|--|---|--------------|--|--|---|---|
| Reference: Ostro et al. (2007, 091354) Location: Monitors in 6 CA counties, some with 2 monitors, for 4 years Particle Size: PM _{2.5} | Subjects NR Exposure: NR | n: NR | Number of constituents considered for grouping: 15 elements, EC, OC; NO ₃ , SO ₄ , PM _{2.5} mass | Grouping method: No grouping was performed # of groups: NA | Groups/ Factors/ Sources: NR | PM variables used: Mass contribution of every constituent |
| Results: Effects were greater during the winter months. In the all year analysis, at 3-day lag associations observed for EC, OC, NO ₃ and Zn. During winter months (Oct -March) effects observed for most species for both all-cause and cardiovascular mortality at lag 3 (EC, OC, SO ₄ , Ca, Fe, K, Mn, Pb, S, Si, Ti, Zn) and (OC, NO ₃ , SO ₄ , Fe, Mn, S, V, Zn), respectively. | | | | | | |
| Reference: Ostro et al. (2009, 191971) Location: Monitors in 6 CA counties, some with 2 monitors/4 years Particle Size: PM _{2.5} | Subjects NR Exposure: NR | n: NR | Number of constituents considered for grouping: 9 elements, EC, OC, PM _{2.5} mass, SO ₄ , NO ₃ | Grouping method: No grouping was performed # of groups: NA | Groups/ Factors/ Sources: NR | PM variables used: Mass contribution of every constituent |
| Results: The following associations were observed with cardiovascular mortality: PM _{2.5} (lag 3); EC (lag 2); NO ₃ (lag 3); SO ₄ (lag 3); Fe (lag 2); K (lag 2); S (lag 3); Ti (lag 2); Zn (lag 3). | | | | | | |
| Reference: Peng et al. (2009, 191998) Location: 119 urban communities STN data/2000-2006 Particle Size: PM _{2.5} | Subjects: Medicare enrollees 65 or older Exposure: NR | n: NR | Number of constituents considered for grouping: SO ₄ , NO ₃ , Si, EC, OCM, Na, NH ₄ | Grouping method: NR # of groups: NR | Groups/Factors/ Sources: Only suggested in discussion | PM variables used: Tracers |
| Results: CVD HA's: EC associated with same-day CVD HA's in single and multi-pollutant models. In single pollutant models associations also observed for sulfate, nitrate, OCM, and ammonium. However, the sulfate, nitrate, OCM, and ammonium associations were reduced in the multi-pollutant models. Respiratory HA's: OCM associated with same-day respiratory HA's in single and multi-pollutant models. Some evidence for sulfate associations at one and two-day lag. | | | | | | |
| Reference: Penttinen et al. (2006, 087988) Location: Helsinki 1996-1997 (7 months) Particle Size: PM _{2.5} | Subjects: Adult asthma subjects, max 2 km from single monitor Exposure: NR | n: 78 | Number of constituents considered for grouping: Unknown | Grouping method: PCA # of groups: 6 | Groups/Factors/ Sources: Long range (PM mass, S, K, Zn), local combustion-traffic (Cu, Zn, Mn, Fe), soil (Si, Al, Ca, Fe, Mn), oil (V, Ni), salt (Na, Cl), unidentified | PM variables used: every component individually, then groupings |
| Results: Long range PM _{2.5} associated with decreased mean PEF in the morning at lag 1. Local combustion PM _{2.5} associated with decreased mean PEF in the evening for lag 1. Local combustion PM _{2.5} associated with decreased mean PEF in the afternoon and evening for 5-day mean lag. Negative significant association between long-range PM _{2.5} and asthma symptom prevalence at lag 3. Sea-salt PM _{2.5} negatively associated with bronchodilator use at lag 3 and 5-day mean lag. Sea-salt PM _{2.5} negatively associated with corticosteroid use for 5-day mean lag. Unidentified PM _{2.5} negatively associated with corticosteroid use at lag 1. Most consistent negative responses for local combustion, although not always significant. No consistent or significant associations between 5-day average concentrations of elements and PEF, cough, asthma symptoms, or medication use. | | | | | | |
| Reference: Riediker et al. (2004, 091261) Location: Inside 9 state police patrol cars Particle Size: PM _{2.5} | Subjects: Healthy male young police officers Exposure: 4 consecutive days | n: 9 | Number of constituents considered for grouping: 10 elements; 3 gaseous pollutants; 2 physical variables | Grouping method: PCA # of groups: 4 when 13+2 constituents included; 3 when only 9 "PM-associated" constituents included | Groups/ Factors/ Sources: Soil; automotive steel wear; gasoline combustion; speed-changing traffic | PM variables used: Mass contribution or score of sources |
| Results: Using two different factor analysis models found most significant effects (MCL, SDNN, PNN50, supraventricular ectopic beats, % neutrophils, % lymphocytes, MCV, von Willebrand Factor, and protein C) were for "speed-change factor" (i.e., Cu, S, aldehydes). Some associations observed for "crustal" and none for "steel wear" and "gasoline." | | | | | | |

| Reference: Sarnat et al. (2008, 097972) Location: 1 monitor in Atlanta. GA for 2 yrs Particle Size: PM _{2.5} | Subjects: NR Exposure: NR | n: NR | Number of constituents considered for grouping: NR | Grouping method: Comparison of: PMF, CMB-LGO, “a priori decision” # of groups: 9, 11 (6 of them common between methods) | Groups/ Factors/ Sources: gasoline, diesel, wood smoke/ biomass burning, soil, secondary SO ₄ /ammonium sulfate, secondary nitrate/ ammonium nitrate, metal processing, railroad, bus and highway, cement kiln, power plants, other OC, ammonium bisulfate | PM variables used: Mass contribution or score of sources, and tracers |
| Results: Sulfate secondary associated with 1.2 - 2.0% increase in RD visits, significant negative association RD visits and primary emissions from coal-fired power plants. CVD significantly associated with other OC (1.014), biomass (1.033), diesel and gas for CMB-LGO. For PMF and CVD visits: diesel (1.025), gas, wood smoke, metal processing (1.013). Year-long associations: PMF diesel, EC, CMB-LGO gas, Zn and biomass combustion sources (CMB-LGO biomass burning, PMF wood smoke, and K). Diesel and gas sources association with RD in the warm season (1.2-2.1% per IQR). | | | | | | |
| Reference: Schreuder et al. (2006, 097959) Location: 1 monitor in Spokane, WA for 7 years Particle Size: PM _{2.5} | Subjects: NR Exposure: NR | n: NR | Number of constituents considered for grouping: 11 elements, TC, NO ₃ | Grouping method: Comparison of: PMF, UNMIX, Multilinear Engine # of groups: 8 | Groups/ Factors/ Sources: Vegetative burning; As-rich Vehicle; SO ₄ ; NO ₃ ; Soil; Cu-rich; Marine | PM variables used: Tracers: TC (vegetative burning); As (As-rich); Zn (vehicle); Si (soil) |
| Results: Si, As, and Zn were not associated with any health outcomes; while an IQR increase in TC (vegetative burning) was associated with a 2% increase in respiratory ED visits. | | | | | | |
| Reference: Tsai et al. (2000, 006251) Location: 3 NJ sites for 2 summers (ATEOS study) Particle Size: NR | Subjects: NR Exposure: NR | N: NR | Number of constituents considered for grouping: 8 metals, IPM, FPM, SO ₄ , CX, DCM, ACE, CO | Grouping method: Unspecified type of factor analysis # of groups: 5 | Groups/ Factors/ Sources: Oil burning, motor emissions, resuspended dust, secondary aerosol, industrial sources | PM variables used: individual constituents, then factor scores, then tracers |
| Results: RR associated with 10 µg/m ³ increases: Newark - 1.03 for industrial and total daily deaths; 1.02 for sulfate and total daily deaths; 1.04 for sulfate and cardiopulmonary deaths. Camden - 1.11 for oil burning sources and total daily deaths; 1.10 industrial and total daily deaths; 1.12 for oil burning sources and cardiopulmonary daily deaths; 1.02 for sulfate and cardiopulmonary daily deaths | | | | | | |
| Reference: Yue et al. (2007, 097968) Location: 1 monitor in German city, 30,000 samples Particle Size: UF/PM _{2.5} | Subjects: Adult males Exposure: CAD | n: 56, data collected 12 times over 6 month for every subject, but extended period of missing PM data | Number of constituents considered for grouping: Apportionment based on particle size distribution. | Grouping method: PMF # of groups: 5 | Groups/ Factors/ Sources: Airborne soil, local traffic, local fuel combustion, remote traffic (diesel), secondary aerosols | PM variables used: Mass contribution or score of sources |
| Results: Overall, repolarization parameters influenced by traffic-related particles; vWF increased in response to traffic-related particles and combustion-generated aerosols. All source factors contributed to increasing CRP levels. | | | | | | |

| Study: Gong et al. (2003, 042106) Location: Los Angeles, CA Particle Size: PM _{2.5} | Subjects: Adult 18-45, healthy vs. asthmatic Exposure: CAPs, healthy and asthmatic subjects exposed at different times | N: 12 healthy, 12 asthmatic | Constituents considered for grouping: 7 elements, EC, NO ₃ , SO ₄ | Grouping method: PCA # of groups: 4 (note: OC data was unavailable) | Groups/ Factors/ Sources: Crustal (Al Si CA K Fe), S (2 metrics of SO ₄ + elemental S), Total Mass + NO ₃ , EC | PM variables used: Total mass, then tracers: SO ₄ , EC, Fe |
|--|---|------------------------------------|--|--|---|--|

| | | | | | | |
|--|---|------------------------------|---|---|--|--|
| Results: Fe and EC associated with a decrease in ST-segment voltage 2 days post-exposure. EC associated with an increase in ST-segment voltage immediately following exposure. Sulfate content associated with a decrease in systolic BP 4 h post-exposure. | | | | | | |
| Study: Gong et al. (2005, 087921) Location: Los Angeles, CA Particle Size: PM _{2.5} | Subjects: Elderly, COPD vs. healthy/ CAPs Exposure: NO ₂ (full factorial) | N: 6 healthy, 18 COPD | Constituents considered for grouping: 7 elements + EC | Grouping method: PCA # of groups: 3 (note: OC was unavailable) | Groups/ Factors/ Sources: Crustal (Al Si CA K Fe), S (= SO ₄), Na | PM variables used: Total mass, then tracers: SO ₄ , Si, Fe, EC |
| Results: Mass concentration of CAPs not observed to significantly affect lung function. However, sulfate content was associated with a decrease lung function (FEV ₁ and FVC), which was enhanced by coexposure to NO ₂ . | | | | | | |
| Reference: Huang et al. (2003, 087377) Location: Chapel Hill, NC Particle Size: PM _{2.5} | Subjects: Healthy adults Exposure: CAPs | N: 35 male; 2 female | Constituents considered for grouping: 8 elements and SO ₄ | Grouping method: PCA # of groups: 2 | Groups/ Factors/ Sources: Fe/SO ₄ /Se/V/Zn/Cu | PM variables used: Factor scores, then mass contribution of all 9 constituents |
| Results: Associations observed between sulfate, Zn, and Se content and increases in BAL neutrophils. Increases in fibrinogen associated with Cu, Zn, and V content. | | | | | | |
| Reference: Urch et al. (2004, 055629) Location: Toronto, Canada Particle Size: PM _{2.5} | Subjects: Healthy adults 19-50 yrs/CAPs Exposure: O ₃ | N: 23 | Constituents considered for grouping: unknown | Grouping method: No grouping was performed # of groups: NA | Groups/ Factors/ Sources: NR | PM variables used: Every constituent in univariate analysis, then OC and SO ₄ in multivariate analysis |
| Results: CAPs-induced increase in diastolic BP significantly associated with carbon content of the particles. | | | | | | |
| Reference: Urch et al. (2004, 055629) Location: Toronto, Canada Particle Size: PM _{2.5} | Subjects: Healthy adults/CAPs Exposure: O ₃ | N: 24 | Constituents considered for grouping: 14 elements, EC, OC | Grouping method: No grouping was performed # of groups: NA | Groups/ Factors/ Sources: NR | PM variables used: Every constituent in univariate analysis, then OC and SO ₄ in multivariate analysis |
| Results: Both organic and EC content of CAPs associated with an increase in brachial artery vasoconstriction. | | | | | | |

| | | | | | | |
|--|--|--|--|---|--|---|
| Reference: Batalha et al. (2002, 088109) Location: Boston, MA Particle Size: PM _{2.5} | Subjects: Rats Exposure: CAPs (3-day mean CAPs concentration range: 126.1-481.0 µg/m ³) CAPs (3-day mean CAPs concentration range: 126.1-481.0 µg/m ³) | n: 7-10 rats × 2 levels CAPs × 2 levels SO ₂ × 6 runs in different seasons | Constituents considered for grouping: 20 elements; OC; EC | Grouping method: Previous study in same city (Clarke et al.), and PCA of this experiment's data # of groups: 4 | Groups/ Factors/ Sources: V/Ni, S, Al/Si, Br/Pb | PM variables used: 4 tracers (Si, SO ₄ , V, Pb) and EC, OC in univariate step. 4 tracers (Si, SO ₄ , V, Pb) in multivariate step |
| Results: Univariate analyses for first day not significant for L/W ratio. Univariate analyses for second and third day and second + third day mean were similar. Presented second + third day mean regression data. CAPs mass, Si, Pb, SO ₄ , EC, OC significant for decreased L/W ratio in normal + CB rats exposed to CAPs. Si, SO ₄ significant for decreased L/W ratio in normal rats. Si, OC significant for decreased L/W ratio in CB rats. Multivariate analysis using normal + CB rats for Si, SO ₄ , V, Pb - only Si remained significant with decreased L/W ratio. | | | | | | |
| Reference: Becker et al. (2005, 088590) Location: Chapel Hill, NC; repeated | Subjects: Normal human bronchial epithelial and human AM Exposure: (2-3X10 ⁵ cells/mL; 11 or 50 µg/mL) | n: NR | Constituents considered for grouping: 12 elements | Grouping method: PCA # of groups: 2 | Groups/ Factors/ Sources: Cr/Al/Si/Ti/Fe/Cu ("crustal"), Zn/As/V/Ni/Pb/Se | PM variables used: NR |

| | | | | | | |
|--|---|---|---|---|---|--|
| sampling for 1 year | Results: Cr/Al/Si/Ti/Fe/Cu associated with IL-8 release in normal human bronchial epithelial cells and IL-6 release in AM. Zn/As/V/Ni/Pb/Se not associated with any endpoints. Stepwise linear regression with individual constituents Fe and Si associated with IL-6 release in AM. Cr associated with IL-8 release in NHBE cells. | | | | | |
| Particle Size: PM ₁₀ | | | | | | |
| Reference: Clarke et al. (2000, 013252) | Subjects: Dogs | n: 10 dogs, 20 paired exposures, 24 crossover | Constituents considered for grouping: 19 elements, black C | Grouping method: PCA # of groups: 4 for exposure in paired runs, 6 for exposure in crossover runs | Groups/ Factors/ Sources: V/Ni, S, Al/Si, Br/Pb, S, Na/Cl Cr | PM variables used: All elements, then factor scores |
| Location: Boston, MA | Exposure: CAPs (average for all studies, paired: 203.4, crossover: 360.8 $\mu\text{g}/\text{m}^3$) repeated exposure with several weeks in between | | | | | |
| Particle Size: PM _{2.5} | Results: No significant differences between baseline, sham, or CAPs group for BAL cell differential percentages. Total BAL protein increased with CAPs compared to sham. No significant hematological effects with CAPs exposure. Mixed linear regression analyses (statistics not provided): Al and Ti (3-day avg. concentrations) associated with dose-dependent decreases in BAL AM and increases in BAL PMN percentages. Sulfate associated with increased WBC. BC, Al, Mn, Si, Zn, Ti, V, Fe, Ni associated with increased blood PMN. Na associated with increased blood lymphocytes. Al, Mn, Si associated with decreased blood lymphocytes. CAPs mass and BC associated with decreased blood eosinophils. CAPs mass associated with decreased platelet count. Regression using results of factor analysis: None for 3-day avg. concentration for BAL parameters. V/Ni for increased AM percentage and Br/Pb for increased PMN percentage for 3rd-day only concentration. V/Ni and Al/Si for increased blood PMN percentage and decreased blood lymphocyte percentage. Al/Si also for increased WBC counts. Na/Cl for increased blood lymphocyte percentage. S for decreased RBC and hemoglobin. | | | | | |
| Reference: Duvall et al. (2008, 097969) | Subjects Primary human airway epithelial cells (100,000 cells/mL; dose not provided) | n: NR | Constituents considered for grouping: NR | Grouping method: CMB, but not on coarse and ultrafine # of groups: 6 or 7 | Groups/ Factors/ Sources: Mobile, residual, oil, wood, soil, secondary SO ₄ , secondary NO ₃ | PM variables used: Mass contribution of constituents, then mass contribution of sources |
| Location: 5 US cities | Exposure: NR | | | | | |
| Particle Size: PM _{2.5} | Results: Linear regression with individual constituents: Sulfate associated with increased IL-8 mRNA expression. Sr associated with increased COX-2 and decreased HO-1 mRNA expressions. K associated with decreased HO-1 mRNA expression. Linear regression with sources: Significance levels not provided. | | | | | |
| Reference: Godleski et al. (2002, 156478) | Subjects: Rats | n: 7-10 rats \times 2 levels CAPs \times 2 levels SO ₂ \times 6 runs in different seasons | Constituents considered for grouping: 20 elements, OC, EC | Grouping method: Previous study in same city (Clarke et al.), and PCA of this experiment's data # of groups: 4 | Groups/ Factors/ Sources: V/Ni, S, Al/Si/Ca, Br/Pb | PM variables used: 4 tracers (I, SO ₄ , V, Pb) and EC, OC |
| Location: Boston, MA | Exposure: CAPs (3-day mean CAPs concentration range: 126.1-481.0 $\mu\text{g}/\text{m}^3$) | | | | | |
| Particle Size: NR | Results: Increased percent of PMNs in BALF in CAPs-exposed rats at 24 h. CAPs affected lung tissue mRNA involved in pro-inflammation, immune, and vascular endothelial responses. Linear regression: Increased PMN associated with CAPs mass, Br, Pb, SO ₄ , EC, and OC. | | | | | |
| Reference: Gurgueira et al. (2002, 036535) | Subjects Rats (Sprague Dawley) | n: 13 experiments (1 rat/group at each time point) | Constituents considered for grouping: 20 elements | Grouping method: No grouping was performed # of groups: NA | Groups/ Factors/ Sources: NR | PM variables used: Mass contribution of every constituent |
| Location: Boston, MA | Exposure: CAPs (avg. mass concentration 600 $\mu\text{g}/\text{m}^3$); also carbon black and ROFA | | | | | |
| Particle Size: PM _{2.5} | Results: Increased oxidative stress in heart and lungs following CAPs exposure (and ROFA exposure). Univariate regression: Mn, Zn, Fe, Cu, and Ca most significant responses for lung ($r^2 > 0.40$). Al, Si, Ti, Fe, and total mass most significant response for heart ($r^2 > 0.49$). | | | | | |
| Reference: Kodavanti et al. (2005, 087946) | Subjects Rats (SH and WKY) | n: 6 1-day, 1-strain runs, 7 2-day, 2-strain runs, 4-9 rats per run. | Constituents considered for grouping: NR | Grouping method: No grouping was performed # of groups: NA | Groups/ Factors/ Sources: NR | PM variables used: Mass contribution of every constituent |
| Location: RTP, NC | Exposure: CAPs (144-2758 $\mu\text{g}/\text{m}^3$) | | | | | |
| Particle Size: PM _{2.5} | Results: No significant correlations between biologic responses and exposure variables (i.e., CAP mass, OC, inorganic C, sulfate, and other major elemental constituents). Al, Cu, Zn correlated with biologic responses when constituents normalized per unit mass of CAP ($\mu\text{g}/\text{mg}$). Zn correlated with plasma fibrinogen in SH rats ($p = 0.0023$). | | | | | |

| Reference: Lippmann et al. (2005, 087453) Location: Rural location upwind from NYC Particle Size: PM _{2.5} | Subjects: Mice (C57 and ApoE) Exposure: CAPs (avg. mass concentration 113 µg/m ³) | n: C57: 3-6 mice/group ApoE ^{-/-} : 9-10 mice/group | Constituents considered for grouping: 19 elements + OC, EC, NO ₃ | Grouping method: (Absolute) PCA # of groups: 4 | Groups/ Factors/ Sources: Regional SO ₄ (S/Si/OC); Resuspended soil (CA/Fe/Al/Si);RO power plants (V/Ni/Se); Traffic and unknown | PM variables used: Mass contribution of sources |
| Results: ApoE null mice: Resuspended soil associated with decreased HR during exposure, but increased HR after exposure. Secondary sulfate associated with decreased HR after exposure. Residual oil associated with increased RMSSD and SDNN in afternoon following exposure. Secondary sulfate associated with decreased RMSSD and SDNN in night following exposure. Resuspended soil associated with increased RMSSD at night following exposure. PM mass associated with decreased HR during exposure and decreased RMSSD at night following exposure. C57 mice: Motor vehicle/other source category associated with decrease in RMSSD in afternoon following exposure | | | | | | |
| Reference: Lippmann et al. (2006, 091165) Location: Rural location upwind from NYC Particle Size: PM _{2.5} | Subjects: Mice (ApoE ⁺) Exposure: CAPs (avg. mass concentration 85.6 µg/m ³) | n: 12 ApoE ⁺ mice (6/group) | Number of constituents considered for grouping: NR | Grouping method: No grouping was performed # of groups: NR | Groups/ Factors/ Sources: NR | PM variables used: Mass contribution of every constituent in CAPs portion of study, contribution of 16 constituents in epi portion |
| Results: Lag for HR elevations on 14 days with wind from NW was same day. Lag for SDNN reduction on 14 days with wind from NW was 0, 1 and 2. GAM analysis: B coefficient significant for Ni and HR (but not V, Cr, or Fe). B coefficient significant for Ni and log SDNN (but not V, Cr, or Fe). | | | | | | |
| Reference: Maciejczyk and Chen (2005, 087456) Location: Rural; upwind from NYC Particle Size: PM _{2.5} | Subjects: NR Exposure: CAPs (90000/well; 300 µg/mL) | n: 110 samples | Constituents considered for grouping: 19 elements + OC, EC, NO ₃ | Grouping method: (Absolute) PCA # of groups: 4 | Groups/ Factors/ Sources: Regional SO ₄ Soil; Unknown Oil combustion | PM variables used: Mass contribution of sources |
| Results: Correlation: V and Ni positively correlated with NF-αB. Oil combustion correlated the greatest with NF-αB (0.316). Significance not provided. Only 2% of mass contribution originates from this source. | | | | | | |
| Reference: Nikolov et al. (2008, 156808) Location: Boston, MA Particle Size: NR | Subjects: Dogs Exposure: | n: 8 dogs, 24 exposure-days in 1997-98; 4 dogs, 21 exposure-days in 2001-02 | Constituents considered for grouping: 13 elements, BC, EC, OC | Grouping method: Compared 3 factor-analytic models within a SEM model # of groups: 4 | Groups/ Factors/ Sources: Oil Combustion V/Ni; Power Plants S ;Road dust Al/Si ;Motor vehicles BC/OC/EC | PM variables used: Mass contribution of every constituent |
| Results: Univariate response for respiratory outcomes: road dust and oil combustion associated with decreased respiratory frequency; motor vehicles associated with increased respiratory frequency; motor vehicles associated with increased PEF; road dust associated with decreased penh and motor vehicles associated with increased penh. Multivariate responses for respiratory outcome: Road dust associated with decreased respiratory rate; Motor vehicles associated with increased airway irritation. | | | | | | |
| Reference: Rhoden et al. (2004, 087969) Location: Boston, MA Particle Size: PM _{2.5} | Subjects: Rats (Sprague Dawley) Exposure: CAPs (avg. mass concentration range 150-2520 µg/m ³) acetylcysteine full factorial | n: 4-8 rats (1-2 per group - sham, CAPs, sham/NAC, CAP/NAC) 10 exposures | Constituents considered for grouping: 20 elements | Grouping method: No grouping was performed # of groups: NA | Groups/ Factors/ Sources: NR | PM variables used: Mass contribution of every constituent |
| Results: Increased oxidative stress and inflammation in lungs of CAPs animals that was attenuated with NAC. Univariate regression: Al, Si, Fe, K, Pb, and Cu most significantly correlated with lung TBARS. No significant correlations for lung carbonyls or lung PMN. | | | | | | |

| | | | | | | |
|---|--|--|---|---|---|---|
| Reference: Saldiva et al. (2002, 025988) Location: Boston, MA Particle Size: PM _{2.5} | Subjects: Rats (Sprague Dawley) Exposure: CAPs (3-day avg. mass concentration range 126.1-481 µg/m ³) | n: 7-10 rats/group (air/sham, SO ₂ /sham, air/CAP, SO ₂ /CAP) × 6 runs in different seasons | Constituents considered for grouping: 15 elements (used Clarke 2000 to select tracers) | Grouping method: Previous study in same city (Clarke et al. 2000) # of groups: 6 | Groups/ Factors/ Sources: V/Ni S Al/Si Br/Pb _____ Na/Cl Cr | PM variables used: Mass contribution of 8 elements in univariate step. Tracers (Si, SO ₄ , V, Pb, Br, Cl) and EC, OC in multivariate step. |
| Results: Increased percent and number of PMN in majority of air and SO ₂ rats exposed to CAPs, but significance levels not provided. Other responses (protein, LDH, NAG) were variable and depended upon the CAPs exposure. No CAPs effect on histopathology. Linear regression: V, Br, Pb, SO ₄ , EC, OC, Si, CAP mass associated with increased PMN and lymphocytes for normal + CB rats. Only V not associated with PMN in normal rats. Lymphocyte response due to CB rats, but not observed for SO ₄ , Si, or mass in this group. Br, Pb, SO ₄ , EC, OC, Si associated with increased total protein in CB rats. Cl and V associated with decreased LDH in CB rats. No BAL effects in normal rats exposed to CAPs. V, Br, Pb, EC, OC, and Cl associated with increased neutrophil density in lungs of normal rats. | | | | | | |
| Reference: Seagrave et al. (2006, 091291) Location: 4 SE US sites for 2 seasons Particle Size: PM _{2.5} | Subjects: Rats (Fisher 344) Exposure: 0.75, 1.5 and 3 mg/rat via intratracheal instillation | n: 5 rats/dose | Constituents considered for grouping: NR | Grouping method: CMB # of groups: 13 | Groups/ Factors/ Sources: secondary NO _x ; secondary NH ₄ ; secondary SO ₄ ; coke production; vegetative detritus; natural gas combust; road dust; wood combust; meat cooking gasoline; diesel other OM; other mass | PM variables used: Mass contribution of every constituent, then mass contribution of sources |
| Results: Potency depended upon season and site of sample collection. In general, effects were greater in the winter. PLS analysis: 2 major constituents identified (OC, Pb, hopanes/steranes, nitrate, As for first and major metal oxides for the second), gasoline most important predictor for both constituents, with diesel influencing second constituent and nitrate influencing first constituent. First constituent affected cytotoxic responses, second constituent affected inflammatory responses. | | | | | | |
| Reference: Veranth et al. (2006, 087479) Location: 8 sites in the Western US Particle Size: PM _{2.5} | Subjects: BEAS-2B cells (35000 cells/cm ² ; 10, 20, 40, 80 µg/cm ²) Exposure: Loose surface soil sweepings through mechanical tumbler and cascade impactor | n: 6; 16 runs over 6 months. | Constituents considered for grouping: 13 elements, TC, 5 OC variables, 4 EC variables, 2 ions, EU, one ratio (Ca: Al), OP, CO ₃ | Grouping method: PLS # of groups: NR | Groups/ Factors/ Sources: NR | PM variables used: Mass contribution every constituent (?) |
| Results: Dose-related increase in IL-6 and decreases in cell viability for all soil types. IL-8 responses more variable and dependent upon soil type. Univariate correlations. Low correlations for all constituents tested with IL-6. Highest correlations for EC1 (R ² = 0.50) and pyrolyzed OC (R ² = 0.46), then Ca/Al (R ² = 0.21). Carbonate carbon, EC3, and Sr correlated with IL-8 (R ² = 0.27, 0.13, and 0.25, respectively). EC and Ni correlated with IL-8 trend over the range of 10-80 µg/cm ² (R ² = 0.39 and 0.27, respectively). Multivariate redundancy analysis OC1, OC3, OC2, EC2, Br, EC1, Ni correlated with IL-8 release, decreased viability, and decreased IL-6 at low and high doses. Ni, EC1, and EC2 correlated with IL-6 release at the high dose, decreased IL-6 at the low dose, decreased IL-8 release, and decreased viability. Br was negatively associated. | | | | | | |
| Reference: Wellenius et al. (2003, 055891) Location: Boston, MA Particle Size: PM _{2.5} | Subjects: Dogs Exposure: CAPs (avg. mass concentration range 161.3-957.3 µg/m ³) repeated exposure with several weeks in between | n: 6 dogs, 20 exposures | Constituents considered for grouping: 15 elements (+ EC OC?) (used Clarke et al. 2000) | Grouping method: Previous study in same city (Clarke et al. 2000) # of groups: 6 (but did not use all in analysis of health effects) | Groups/ Factors/ Sources: V/Ni S Al/Si Br/Pb _____ Na/Cl Cr | PM variables used: Univariate: Mass Number Ni, S, Si, BC Multivariate: Ni, S, Si, BC |
| Results: ST-segment elevation increased with CAPs. Univariate regression: Si and Pb associated with peak ST-segment elevation and integrated ST-segment change. CAPs mass or number concentration were not associated with any change. Multivariate regression: Si associated with peak ST-segment elevation and integrated ST-segment change. | | | | | | |

| | | | | | | |
