## POST-AGENCY REVIEW DRAFT-DO NOT CITE OR QUOTE APPENDIX H

## H.1. Lifetable Analysis:

A spreadsheet illustrating the extra risk calculation for the derivation of the $\mathrm{LEC}_{01}$ for RCC incidence is presented in Table $\mathrm{H}-1$.

## POST-AGENCY REVIEW DRAFT-DO NOT CITE OR QUOTE

Table H-1. Extra risk calculation ${ }^{\text {a }}$ for environmental exposure to 1.82 ppm TCE (the $\mathbf{L E C}_{01}$ for RCC
incidence) ${ }^{\text {b }}$ using a linear exposure-response model based on the categorical cumulative exposure results of Charbotel et al. (2006), as described in Section 5.2.2.1.2.

## POST-AGENCY REVIEW DRAFT-DO NOT CITE OR QUOTE

Column A: interval index number (i).
Column B: 5-year age interval (except $<1$ and $1-4$ ) up to age 85.
Column C: all-cause mortality rate for interval i ( $\times 10^{5} /$ year) ( 2004 data from NCHS).
Column D: RCC incidence rate for interval i ( $\times 10^{5} /$ year) (2001-2005 SEER data).
Column E: all-cause hazard rate for interval $\mathrm{i}\left(\mathrm{h}_{\mathrm{i}}\right)\left(=\right.$ all-cause mortality rate $\times$ number of years in age interval). ${ }^{\text {c }}$
Column F: probability of surviving interval i without being diagnosed with RCC $\left(q_{i}\right)\left(=\exp \left(-h_{i}^{*}\right)\right)$.
Column $G$ : probability of surviving up to interval $i$ without having been diagnosed with $R C C\left(S_{i}\right)\left(S_{1}=1 ; S_{i}=S_{i-1} \times q_{i-1}\right.$, for $\left.i>1\right)$.
Column H: RCC incidence hazard rate for interval $\mathrm{i}\left(\mathrm{h}_{\mathrm{i}}\right)(=$ RCC incidence rate $\times$ number of years in interval).
Column I: conditional probability of being diagnosed with RCC in interval i $\left(=\left(h_{i} / h_{i}\right) \times S_{i} \times\left(1-q_{i}\right)\right)$, i.e., conditional upon surviving up to interval i without having been diagnosed with RCC [Ro, the background lifetime probability of being diagnosed with $\mathrm{RCC}=$ the sum of the conditional probabilities across the intervals].
Column J: exposure duration (in years) at mid-interval (xtime).
Column K: cumulative exposure mid-interval (xdose) ( $=$ exposure level (i.e., 1.82 ppm ) $\times 365 / 240 \times 20 / 10 \times$ xtime $)[365 / 240 \times 20 / 10$ converts continuous environmental exposures to corresponding occupational exposures].
Column L: RCC incidence hazard rate in exposed people for interval $i\left(h x_{i}\right)\left(=h_{i} \times(1+\beta \times x\right.$ dose $)$, where $\left.\beta=0.001205+(1.645 \times 0.0008195)=0.002554\right)$ [0.001205 per ppm $\times$ year is the regression coefficient obtained from the weighted linear regression of the categorical results (see Section 5.2.2.1.2). To estimate the $\mathrm{LEC}_{01}$, i.e., the $95 \%$ lower bound on the continuous exposure giving an extra risk of $1 \%$, the $95 \%$ upper bound on the regression coefficient is used, i.e., MLE $+1.645 \times$ SE].
Column M: all-cause hazard rate in exposed people for interval $i\left(h x_{i}\right)\left(=h *_{i}+\left(h x_{i}-h_{i}\right)\right)$.
Column $N$ : probability of surviving interval $i$ without being diagnosed with RCC for exposed people $\left(q x_{i}\right)\left(=\exp \left(-h^{*} x_{i}\right)\right)$.
Column O: probability of surviving up to interval $i$ without having been diagnosed with RCC for exposed people $\left(\mathrm{Sx}_{\mathrm{i}}\right)\left(\mathrm{Sx}_{1}=1\right.$; $\mathrm{Sx}_{\mathrm{i}}=\mathrm{Sx}_{\mathrm{i}-1} \times \mathrm{qx}_{\mathrm{i}-1}$, for $\mathrm{i}>1$ ).
Column $P$ : conditional probability of being diagnosed with RCC in interval i for exposed people $\left(=\left(h x_{i} / h^{*} x_{i}\right) \times S x_{i} \times\left(1-q x_{i}\right)\right)$ [Rx, the lifetime probability of being diagnosed with RCC for exposed people $=$ the sum of the conditional probabilities across the intervals].
${ }^{\text {a }}$ Using the methodology of BEIR IV (1988).
${ }^{\text {b }}$ The estimated $95 \%$ lower bound on the continuous exposure level of TCE that gives a $1 \%$ extra lifetime risk of RCC.
${ }^{c}$ For the cancer incidence calculation, the all-cause hazard rate for interval i should technically be the rate of either dying of any cause or being diagnosed with the specific cancer during the interval, i.e., (the all-cause mortality rate for the interval + the cancer-specific incidence rate for the interval-the cancer-specific mortality rate for the interval [so that a cancer case isn't counted twice, i.e., upon diagnosis and upon death]) $\times$ number of years in interval. This adjustment was ignored here because the RCC incidence rates are small compared with the all-cause mortality rates.
$\mathrm{MLE}=$ maximum likelihood estimate, $\mathrm{SE}=$ standard error.

## H.2. Equations Used for Weighted Linear Regression of Results from Charbotel et al. (2006):

[source: Rothman (1986), p. 343-344]
linear model: $\mathrm{RR}=1+\mathrm{bX}$
where $R R=$ risk ratio, $X=$ exposure, and $b=$ slope
b can be estimated from the following equation:

$$
\hat{b}=\frac{\sum_{j=2}^{n} w_{j} x_{j} R \hat{R}_{j}-\sum_{j=2}^{n} w_{j} x_{j}}{\sum_{j=2}^{n} w_{j} x_{j}^{2}}
$$

where j specifies the exposure category level and the reference category $(\mathrm{j}=1)$ is ignored.
the standard error of the slope can be estimated as follows:

$$
S E(\hat{b}) \approx \sqrt{\frac{1}{\sum_{j=2}^{n} w_{j} x_{j}{ }^{2}}}
$$

the weights, $\mathrm{w}_{\mathrm{j}}$, are estimated from the confidence intervals (as the inverse of the variance):

$$
\operatorname{Var}\left(R \hat{R}_{j}\right) \approx R \hat{R}_{j}{ }^{2} \operatorname{Var}\left[\ln \left(R \hat{R}_{j}\right)\right] \approx R \hat{R}_{j}{ }^{2} \times\left[\frac{\ln \left(\overline{R R}_{j}\right)-\ln \left(\underline{R R}_{j}\right)}{2 \times 1.96}\right]^{2}
$$

where $\overline{R R}_{\mathrm{j}}$ is the $95 \%$ upper bound on the $\mathrm{RR}_{\mathrm{j}}$ estimate (for the jth exposure category) and $\underline{R R}_{\mathrm{i}}$ is the $95 \%$ lower bound on the $R R_{j}$ estimate.
