H.1. Lifetable Analysis:

A spreadsheet illustrating the extra risk calculation for the derivation of the LEC_{01} for RCC incidence is presented in Table H-1.

POST-AGENCY REVIEW DRAFT—DO NOT CITE OR QUOTE

Table H-1. Extra risk calculation^a for environmental exposure to 1.82 ppm TCE (the LEC₀₁ for RCC incidence)^b using a linear exposure-response model based on the categorical cumulative exposure results of Charbotel et al. (2006), as described in Section 5.2.2.1.2.

A	B	C	D	E	F	G	H	I	J	K	L	M	N	O	P

POST-AGENCY REVIEW DRAFT—DO NOT CITE OR QUOTE

Column A: interval index number (i).

Column B: 5-year age interval (except <1 and 1–4) up to age 85.

Column C: all-cause mortality rate for interval i ($\times 10^5/\text{year}$) (2004 data from NCHS).

Column D: RCC incidence rate for interval i ($\times 10^5/\text{year}$) (2001–2005 SEER data).

Column E: all-cause hazard rate for interval i (h^*_i) (= all-cause mortality rate \times number of years in age interval).^c

Column F: probability of surviving interval i without being diagnosed with RCC (q_i) (= $\exp(-h^*_i)$).

Column G: probability of surviving up to interval i without having been diagnosed with RCC (S_i) ($S_1 = 1$; $S_i = S_{i-1} \times q_{i-1}$, for $i > 1$).

Column H: RCC incidence hazard rate for interval i (h_i) (= RCC incidence rate \times number of years in interval).

Column I: conditional probability of being diagnosed with RCC in interval i (= $(h_i/h^*_i) \times S_i \times (1-q_i)$), i.e., conditional upon surviving up to interval i without having been diagnosed with RCC [Ro, the background lifetime probability of being diagnosed with RCC = the sum of the conditional probabilities across the intervals].

Column J: exposure duration (in years) at mid-interval (xtime).

Column K: cumulative exposure mid-interval (xdose) (= exposure level (i.e., 1.82 ppm) $\times 365/240 \times 20/10 \times \text{xtime}$) [$365/240 \times 20/10$ converts continuous environmental exposures to corresponding occupational exposures].

Column L: RCC incidence hazard rate in exposed people for interval i (hx_i) (= $h_i \times (1 + \beta \times \text{xdose})$, where $\beta = 0.001205 + (1.645 \times 0.0008195) = 0.002554$) [0.001205 per ppm \times year is the regression coefficient obtained from the weighted linear regression of the categorical results (see Section 5.2.2.1.2). To estimate the LEC_{01} , i.e., the 95% lower bound on the continuous exposure giving an extra risk of 1%, the 95% upper bound on the regression coefficient is used, i.e., $MLE + 1.645 \times SE$].

Column M: all-cause hazard rate in exposed people for interval i (h^*x_i) (= $h^*_i + (hx_i - h_i)$).

Column N: probability of surviving interval i without being diagnosed with RCC for exposed people (qx_i) (= $\exp(-h^*x_i)$).

Column O: probability of surviving up to interval i without having been diagnosed with RCC for exposed people (Sx_i) ($Sx_1 = 1$; $Sx_i = Sx_{i-1} \times qx_{i-1}$, for $i > 1$).

Column P: conditional probability of being diagnosed with RCC in interval i for exposed people (= $(hx_i/h^*x_i) \times Sx_i \times (1-qx_i)$) [Rx, the lifetime probability of being diagnosed with RCC for exposed people = the sum of the conditional probabilities across the intervals].

^a Using the methodology of BEIR IV (1988).

^b The estimated 95% lower bound on the continuous exposure level of TCE that gives a 1% extra lifetime risk of RCC.

^c For the cancer incidence calculation, the all-cause hazard rate for interval i should technically be the rate of either dying of any cause or being diagnosed with the specific cancer during the interval, i.e., (the all-cause mortality rate for the interval + the cancer-specific incidence rate for the interval—the cancer-specific mortality rate for the interval [so that a cancer case isn't counted twice, i.e., upon diagnosis and upon death]) \times number of years in interval. This adjustment was ignored here because the RCC incidence rates are small compared with the all-cause mortality rates.

MLE = maximum likelihood estimate, SE = standard error.

H.2. Equations Used for Weighted Linear Regression of Results from Charbotel et al. (2006):

[source: Rothman (1986), p. 343-344]

linear model: $RR = 1 + bX$

where RR = risk ratio, X = exposure, and b = slope

b can be estimated from the following equation:

$$\hat{b} = \frac{\sum_{j=2}^n w_j x_j R\hat{R}_j - \sum_{j=2}^n w_j x_j}{\sum_{j=2}^n w_j x_j^2}$$

where j specifies the exposure category level and the reference category ($j = 1$) is ignored.

the standard error of the slope can be estimated as follows:

$$SE(\hat{b}) \approx \sqrt{\frac{1}{\sum_{j=2}^n w_j x_j^2}}$$

the weights, w_j , are estimated from the confidence intervals (as the inverse of the variance):

$$Var(R\hat{R}_j) \approx R\hat{R}_j^2 Var[\ln(R\hat{R}_j)] \approx R\hat{R}_j^2 \times \left[\frac{\ln(\overline{RR}_j) - \ln(\underline{RR}_j)}{2 \times 1.96} \right]^2$$

where \overline{RR}_j is the 95% upper bound on the RR_j estimate (for the j th exposure category) and \underline{RR}_j is the 95% lower bound on the RR_j estimate.
