1.0 Introduction

This report describes EPA's Hierarchical Bayesian model-generated (HBM) estimates of ozone (O3) and fine particulate matter (PM2.5, particles with aerodynamic diameter < 2.5 microns) concentrations throughout the continental United States during the 2007 calendar year. HBM estimates provide the spatial and temporal variance of O_3 and $PM_{2.5}$, allowing estimation of their concentration values across the U.S., independent of where air quality monitors are physically located. HBM estimates are generated through the statistical 'fusion' of measured air quality monitor concentration values and air quality model predicted concentration values from EPA's Community Multiscale Air Quality (CMAQ) computer model. Information on EPA's air quality monitors, CMAQ model, and HBM model is included to provide the background and context for understanding the data output presented in this report.

The data contained in this report are an outgrowth of a collaborative research partnership between EPA scientists from the Office of Research and Development's (ORD) National Exposure Research Laboratory (NERL) and personnel from EPA's Office of Air and Radiation's (OAR) Office of Air Quality Planning and Standards (OAQPS). NERL's Human Exposure and Atmospheric Sciences Division (HEASD), Atmospheric Modeling and Analysis Division (AMAD), and Environmental Sciences Division (ESD), in conjunction with OAQPS, work together to provide air quality monitoring data and model estimates to the Centers for Disease Control and Prevention (CDC) for use in their Environmental Public Health Tracking (EPHT) Network.

CDC's EPHT Network supports linkage of air quality data with human health outcome data for use by various public health agencies throughout the U.S. The EPHT Network Program is a multidisciplinary collaboration that involves the ongoing collection, integration, analysis, interpretation, and dissemination of data from: environmental hazard monitoring activities; human exposure assessment information; and surveillance of noninfectious health conditions. As part of the National EPHT Program efforts, the CDC is leading the initiative to build the National EPHT Network (http://www.cdc.gov/nceh/tracking/default.htm). The National EPHT Program, with the EPHT Network as its cornerstone, is the CDC's response to requests calling for improved understanding of how the environment affects human health. The EPHT Network is designed to provide the means to identify, access, and organize hazard, exposure, and health data from a variety of sources and to examine, analyze and interpret those data based on their spatial and temporal characteristics. The EPHT Network is a standards-based, secure information network that was created to be used by many different entities, including epidemiologists, public health practitioners, academic researchers, schools of public health, along with local, state, and federal agencies such as EPA. Levels of access to the data in the EPHT Network will vary among stakeholders based upon their role and their purpose for using the data. Data access will be carefully controlled to ensure compliance with federal and state privacy laws which address the use of health data and other protected personal information. The CDC's National EPHT Program is establishing the EPHT Network by collaborating with a wide range of partners with expertise from federal, state, and local health and environmental agencies; nongovernmental organizations (NGOs); state public health and environmental laboratories; and schools of public health.

Since 2002, EPA has collaborated with the CDC on the development of the EPHT Network. On September 30, 2003, the Secretary of Health and Human Services (HHS) and the Administrator of EPA signed a joint Memorandum of Understanding (MOU) with the objective of advancing efforts to achieve mutual environmental public health goals.[1] HHS, acting through the CDC and the Agency for Toxic Substances and Disease Registry (ATSDR), and EPA agreed to expand their cooperative activities in support of the CDC EPHT Network and EPA's Central Data Exchange Node on the Environmental Information Exchange Network in the following areas:

- Collecting, analyzing and interpreting environmental and health data from both agencies (HHS and EPA).
- Collaborating on emerging information technology practices related to building, supporting, and operating the CDC EPHT Network and the Environmental Information Exchange Network.
- Developing and validating additional environmental public health indicators.
- Sharing reliable environmental and public health data between their respective networks in an efficient and effective manner.
- Consulting and informing each other about dissemination of results obtained through work carried out under the MOU and the associated Interagency Agreement (IAG) between EPA and CDC.

Under the auspices of the HHS/EPA MOU, a research project was implemented between 2004 and 2006 to investigate the utility of EPA-generated air quality estimates as an input to the EPHT Network. The relationship between air pollutants

[1] Available at www.cdc.gov/nceh/tracking/epa_mou.htm

and human health is of interest to both Agencies. EPA develops and funds ambient air quality monitoring networks to monitor air pollution and to provide data that may be used to mitigate its impact on our ecosystems and human health. (Note: AQS and AIRNow are EPA databases containing data collected from EPA's air quality monitoring networks.) Air quality monitoring data has been used by researchers to investigate the linkages between human health outcomes and air quality, and by environmental and public health professionals to develop environmental health indicators which provide measures of potential human health impacts. However, an analysis of the currently available methods for generating and characterizing air quality estimates that could be developed and delivered systematically, and which were also readily available to link with public health surveillance data, had not been previously attempted. EPA collaborated with the CDC and state public health agencies in New York, Maine, and Wisconsin on the Public Health Air Surveillance Evaluation (PHASE) project to address this issue. The project focused on generating concentration surfaces for O_3 and $PM_{2.5}$, which were subsequently linked with asthma and cardiovascular disease data. Results of this research project indicated that using a Hierarchical Bayesian approach to statistically "combine" Community Multiscale Air Quality (CMAQ) model estimates and air quality monitoring data documented in EPA's AQS provided better overall estimates of air quality at locations without monitors than those obtained through other well-known, statistically-based estimating techniques (e.g., kriging).

Ambient air quality monitoring data stored in the Air Quality System (AQS), along with air quality modeling estimates from CMAQ, can be statistically combined, via a Hierarchical Bayesian statistical space-time modeling (HBM) system, to provide air quality estimates (hereafter referred to as Hierarchical Bayesian-derived air quality estimates). These Hierarchical Bayesian-derived air quality estimates serve as well-characterized inputs to the EPHT Network. The air quality monitor data, CMAQ modeling estimates, and the Hierarchical Bayesian-derived air quality estimates can be used to develop meaningful environmental public health indicators and to link ozone and $PM_{2.5}$ concentrations with health outcome data. The Hierarchical Bayesian-derived air quality estimates are based on EPA's current knowledge of predicting spatial and temporal variations in pollutant concentrations derived from multiple sources of information. EPA is continuing its research in this critical science area and is implementing this project to establish procedures for routinely generating the Hierarchical Bayesian-derived air quality estimates developed in the PHASE project. This effort will assist EPA in making both ambient air quality monitoring (raw) data and the Hierarchical Bayesian-derived air quality estimates available to the CDC EPHT Network through EPA's Central Data Exchange (CDX) Node on the Environmental Information Exchange Network.

Because of EPA's expertise related to measurement, analysis, scientific visualization, and reporting of air quality monitoring data, air quality modeling estimates, and Hierarchical Bayesian-derived air quality estimates and associated research, the CDC approached EPA to provide technical support for incorporating air quality data and estimates into its EPHT Network. Because the air quality data generated could be used by EPA to achieve other research goals related to linking air quality data and health effects and performing cumulative risk assessments, EPA proposed an interagency agreement under which each agency would contribute funding and/or in-kind support to efficiently leverage the resources of both agencies. The major objective of this research is to provide data and guidance to CDC to assist them in tracking estimated population exposure to O_3 and $PM_{2.5}$; estimating health impacts to individuals and susceptible subpopulations; guiding public health actions; and conducting analytical studies linking human health outcomes and environmental conditions.

This report is divided into five sections and three appendices. The first section of the report describes the air quality data obtained from EPA's nationwide monitoring network and the importance of the monitoring data in determining potential health risks. The second section of the report details the emissions inventory data, how it is obtained and its role as a key input into air quality computer models. The third section of the report describes the CMAQ computer model and its role in providing estimates of pollutant concentrations across the U.S. based on 12-km grid cells (entire continental U.S.). The fourth section of the report explains the Hierarchical Bayesian statistical modeling system which is used to combine air quality monitoring data and air quality estimates from the CMAQ model into a continuous concentration surface which includes regions without air quality monitors. The fifth section of the report provides guidelines and requisite understanding that users must have when using the Hierarchical Bayesian statistical modeling system. The appendices provide a list of acronyms used in this report, detailed information on emissions inventory data, and detailed information on the Hierarchical bayesian statistical modeling system.

2.0
Air Quality Data

To compare health outcomes with air quality measures, it is important to understand the origins of those measures and the methods for obtaining them. This section provides a brief overview of the origins and process of air quality regulation in this country. It provides a detailed discussion of ozone (O_3) and particulate matter (PM). The PHASE project focused on these two pollutants, since numerous studies found them to be harmful to public health and the environment, and there was more extensive monitoring and modeling data available.

2.1 Introduction to Air Quality Regulation in the United States

2.1.1 The Clean Air Act

In 1970, the Clean Air Act (CAA) was signed into law. Under this law, EPA sets limits on how much of a pollutant can be present in the air anywhere in the United States. This ensures that all Americans have the same basic health and environmental protections. The CAA has been amended several times to keep pace with new scientific information. More information is available on the CAA at: http://www.epa.gov/oar/caa/. Under the CAA, the U.S. EPA has established standards or limits for six common/ubiquitous air pollutants, known as the criteria air pollutants: carbon monoxide (CO), lead (Pb), nitrogen dioxide (NO_2), sulfur dioxide (SO_2), ozone (O_3), and particulate matter (PM). These standards, called the National Ambient Air Quality Standards (NAAQS), are designed to protect public health and the environment. The CAA established two types of air quality standards. Primary standards set limits to protect public health, including the health of "sensitive" populations such as asthmatics, children, and the elderly. Secondary standards set limits to protect public welfare, including protection against decreased visibility, damage to animals, crops, vegetation, and buildings. The law requires EPA to periodically review these standards. More specific information on the NAAQS is available at: http://www.epa.gov/air/criteria.html. General information on the criteria pollutants is available at: http://www.epa.gov/air/urbanair/. When these standards are not met, the area is designated as a nonattainment area. States must develop state implementation plans (SIPs) that explain the regulations and controls it will use to clean up the nonattainment areas. States with an EPA-approved SIP can request that the area be redesignated from nonattainment to attainment by providing three consecutive years of data showing NAAQS compliance. The state must also provide a maintenance plan to demonstrate how it will continue to comply with the NAAQS and demonstrate compliance over a 10-year period, and what corrective actions it will take should a NAAQS violation occur after redesignation. EPA must review and approve the NAAQS compliance data and the maintenance plan before redesignating the area; thus, a person may live in an area designated as non attainment even though no NAAQS violation has been observed for quite some time. More information attainment/non attainment designations is available at: http://www.epa.gov/ozonedesignations/ and http://www.epa.gov/pmdesignations/.

2.1.2 Ozone

Ozone (O_3) is a colorless gas composed of three oxygen atoms. Ground level ozone is formed when pollutants released from cars, power plants, and other sources react in the presence of heat and sunlight. It is the prime ingredient of what is commonly called "smog." When inhaled, ozone can cause acute respiratory problems, aggravate asthma, cause inflammation of lung tissue, and even temporarily decrease the lung capacity of healthy adults. Repeated exposure may permanently scar lung tissue. Toxicological, human exposure, and epidemiological studies were integrated by EPA in "Air Quality Criteria for Ozone and Related Photochemical Oxidants" available at: http://www.epa.gov/ttn/naaqs/standards/ozone/s_o3_index.html. The current (as of October 2008) NAAQS for ozone, in place since 1997, is an 8-hour maximum of 0.075 parts per million [ppm] (for details, see http://www.epa.gov/ozonedesignations/). An 8-hour maximum is the maximum of the 24 possible running 8-hour average concentrations for each calendar day. The Clean Air Act requires EPA to review the NAAQS at least every five years and revise them as appropriate in accordance with Section 108 and Section 109 of the Act. The 'allowable' ozone values are shown in the table below:

Parts Per Million: Measurement—(ppm)	1997	2008
1-Hour Standard	0.12	0.12
8-Hour Standard	0.08	0.075

Table 2-1. Ozone Standard

2.1.3 Particulate Matter (PM)

PM air pollution is a complex mixture of small and large particles of varying origin that can contain hundreds of different chemicals, including cancer-causing agents like polycyclic aromatic hydrocarbons (PAH), as well as heavy metals such as arsenic and cadmium. PM air pollution results from direct emissions of particles as well as particles formed through chemical transformations of gaseous air pollutants. The characteristics, sources, and potential health effects of particulate matter depend on its source, the season, and atmospheric conditions.

As practical convention, PM is divided by sizes[2] into classes with differing health concerns and potential sources. Particles less than 10 micrometers in diameter (PM_{10}) pose a health concern because they can be inhaled and accumulate in the respiratory system. Particles less than 2.5 micrometers in diameter ($PM_{2.5}$) are referred to as "fine" particles. Because of their small size, fine particles can lodge deeply into the lungs. Sources of fine particles include all types of combustion (motor vehicles, power plants, wood burning, etc.) and some industrial processes. Particles with diameters between 2.5 and 10 micrometers ($PM_{10-2.5}$) are referred to as "coarse" or PMc. Sources of PMc include crushing or grinding operations and dust from paved or unpaved roads. The distribution of PM_{10}, $PM_{2.5}$ and PMc varies from the Eastern U.S. to arid western areas.

Epidemiological and toxicological studies have demonstrated associations between fine particles and respiratory and cardiovascular health effects, including irritation of the airways, coughing, decreased lung function, aggravated asthma, development of chronic bronchitis, irregular heartbeat, nonfatal heart attacks, and premature death in people with heart or lung disease. These studies are summarized and integrated in "Air Quality Criteria for Particulate Matter" (EPA 2004). This document and other technical documents related to PM standards are available at http://www.epa.gov/ttn/naaqs/standards/pm/s_pm_index.html.

The current (as of March 2012) NAAQS for $PM_{2.5}$ includes both a 24-hour standard to protect against short-term effects, and an annual standard to protect against long-term effects. The annual average $PM_{2.5}$ concentration must not exceed 15 ug/m^3, and the 24-hr average concentration must not exceed 35 micrograms per cubic meter (ug/m^3). The current annual $PM_{2.5}$ NAAQS was set in 1997 and the current 24-hr $PM_{2.5}$ NAAQS was set in 2006 "(for details see http://www.epa.gov/air/criteria.html) and http://www.epa.gov/oar/particlepollution/naaqsrev2006.html). The EPA quality assurance standards for $PM_{2.5}$ monitors specify that the coefficient of variation (CV = standard deviation/mean) of a monitor measurement must be less than 10%. The relative bias (tendency for measured values to be higher or lower than 'true' value) for $PM_{2.5}$ monitor measurements must be between the range of -10% to +10%. The 'allowable' $PM_{2.5}$ values are shown in the table below:

Micrograms Per Cubic Meter: Measurement - (μg/m3)	1997	2006
Annual Average	15	15
24-Hour Average	65	35

Table 2-2. $PM_{2.5}$ Standards

[2] The measure used to classify PM into sizes is the aerodynamic diameter. The measurement instruments used for PM are designed and operated to separate large particles from the smaller particles. For example, the $PM_{2.5}$ instrument only captures and thus measures particles with an aerodynamic diameter less than 2.5 micrometers. The EPA method to measure PMc is designed around taking the mathematical difference between measurements for PM_{10} and $PM_{2.5}$.

2.2 Ambient Air Quality Monitoring in the United States

2.2.1 Monitoring Networks

The Clean Air Act requires every state to establish a network of air monitoring stations for criteria pollutants, following specific guidelines for their location and operation. Federal Reference Method (FRM) and Federal Equivalent Method (FEM) monitors are used to measure criteria pollutants. The monitoring stations in this network have been called the State and Local Air Monitoring Stations (SLAMS). The SLAMS network consists of approximately 4,000 monitoring sites whose distribution is largely determined by the needs of state and local air pollution control agencies. All ambient monitoring networks selected for use in SLAMS are tested periodically to assess the quality of the SLAMS data being produced. Measurement accuracy and precision are estimated for both automated and manual methods. The individual results of these tests for each method or analyzer are reported to EPA. Then, EPA calculates quarterly integrated estimates of precision and accuracy for the SLAMS data.

The National Air Monitoring Station network (NAMS) is about a 1,000-site subset of the SLAMS network, with emphasis on areas of maximum concentrations and high population density in urban and multi-source areas. The NAMS monitoring sites are designed to obtain more timely and detailed information about air quality in strategic locations and must meet more stringent monitor siting, equipment type, and quality assurance criteria. NAMS monitors also must submit detailed quarterly and annual monitoring results to EPA.

The SLAMS and NAMS networks experienced accelerated growth throughout the 1970s. The networks were further expanded in 1999 following the 1997 revision of the CAA to include separate standards for fine particles ($PM_{2.5}$) based on their link to serious health problems ranging from increased symptoms, hospital admissions, and emergency room visits, to premature death in people with heart or lung disease. While most of the monitors in these networks are located in populated areas of the country, "background" and rural monitors are an important part of these networks. For criteria pollutants other than ozone and $PM_{2.5}$, the number of monitors has declined. More information on SLAMS and NAMS, as well as EPA's other air monitoring networks are available at: http://www.epa.gov/ttn/amtic.

In summary, state and local agencies and tribes implement a quality-assured monitoring network to measure air quality across the United States. EPA provides guidance to ensure a thorough understanding of the quality of the data produced by these networks. These monitoring data have been used to characterize the status of the nation's air quality and the trends across the U.S. (http://www.epa.gov/airtrends).

2.2.2 Air Quality System Database

The Air Quality System (AQS) database contains ambient air pollution data collected by EPA, state, local, and tribal air pollution control agencies from thousands of monitoring stations (SLAMS and NAMS). AQS also contains meteorological data, descriptive information about each monitoring station (including its geographic location and its operator), and data quality assurance and quality control

information. State and local agencies are required to submit their air quality monitoring data into AQS by the end of the quarter following the quarter in which the data were collected. This ensures timely submission of these data for use by state, local, and tribal agencies, EPA, and the public. EPA's Office of Air Quality Planning and Standards and other AQS users rely upon the data in AQS to assess air quality, assist in attainment vs. non-attainment designations, evaluate SIPs, perform modeling for permit review analysis, and perform other air quality management functions.

AQS was converted from a mainframe system to a UNIX-based Oracle system which is easily accessible to users through the Internet. This system became available in January 2002. Today, state, local, and tribal agencies submit their data directly to AQS. Registered users may also retrieve data through the AQS application and through the use of third-party software such as the Discoverer tool from Oracle Corporation. For more detailed information about the AQS database, go to http://www.epa.gov/ttn/airs/airsaqs/index.htm.

2.2.3 Advantages and Limitations of the Air Quality Monitoring and Reporting System

Air quality data is required to assess public health outcomes that are affected by poor air quality. The challenge is to get surrogates for air quality on time and spatial scales that are useful for Environmental Public Health Tracking activities.

The advantage of using ambient data from EPA monitoring networks for comparing with health outcomes is that these measurements of pollution concentrations are the best characterization of the concentration of a given pollutant at a given time and location, and require no further analysis. Furthermore, the data are supported by a comprehensive quality assurance program, ensuring data of known quality. One disadvantage of using the ambient data is that it is usually out of spatial and temporal alignment with health outcomes. This spatial and temporal 'misalignment' between air quality monitoring data and health outcomes is influenced by the following key factors: the living and/or working locations (microenvironments) where a person spends their time not being co-located with an air quality monitor; time(s)/date(s) when a patient experiences a health outcome/symptom (e.g., asthma attack) not coinciding with time(s)/date(s) when an air quality monitor records ambient concentrations of a pollutant high enough to affect the symptom (e.g., asthma attack either during or shortly after a high $PM_{2.5}$ day). To compare/correlate ambient concentrations with acute health effects, daily local air quality data is needed. Spatial gaps exist in the air quality monitoring network, especially in rural areas, since the air quality monitoring network is designed to focus on measurement of pollutant concentrations in high population density areas. Temporal limits also exist. Samples from Federal Reference Method (FRM) $PM_{2.5}$ monitors are generally collected only one day in every three days, due in part to the time and costs involved in collecting and analyzing the samples. However, over the past several years Tapered Element Oscillating Microbalance (TEOM) monitors, which can automatically collect, analyze, and report $PM_{2.5}$ measurements on an hourly basis, have been introduced. These monitors are available in most of the major metropolitan areas and (as of March 2012) are being assessed for their equivalency to the FRM. Ozone is monitored daily, but mostly during the ozone season (the warmer months, approximately April through October). However, year-long data is extremely useful to evaluate whether ozone is a factor in health outcomes during the non-ozone seasons.

2.2.4 Use of Air Quality Monitoring Data for EPHT

Air quality monitoring data has been used to provide the information for the following:

1. Assessing effectiveness of SIPs in addressing NAAQS nonattainment areas
2. Characterizing local, state, and national air quality status and trends
3. Associating health and environmental damage with air quality levels/concentrations

For the EPHT effort, EPA is providing air quality data to support efforts associated with (2), and (3) above. Data supporting (3) is generated by EPA through the use of its air quality data and its Hierarchical Bayesian space-time statistical model (HBM).

Most studies that associate air quality with health outcomes use air monitoring as a surrogate for exposure to the air pollutants being investigated. Many studies have used the monitoring networks operated by state and federal agencies in the implementation of Clean Air Act requirements. Some studies perform special monitoring that can better represent exposure to the air pollutants: community monitoring, near residences, in-house or work place monitoring, and personal monitoring. For the EPHT program, special monitoring is generally not supported, though it could be used on a case-by-case basis.

Many approaches may be used to assign exposure from monitors or estimate concentrations for a new time period or location based on existing data. On the simplest level for example, data from monitoring sites are averaged and applied to the population in an entire county, or the nearest monitor is assigned to a subject's address. At the next level, variogram analysis may be used to describe the spatial correlation of the data and interpolate concentrations across space. Such approaches work well for temporally and spatially robust data, but where data are missing (for example for $PM_{2.5}$ data with samples taken every third day), further assumptions and modeling are needed which add uncertainty into the interpolated concentrations. Finally, air quality monitoring data can be used with air quality modeling estimates (using emissions inventories) and incorporated into a Bayesian model to enhance the prediction of ambient air concentrations in space and time. There are two methods used in EPHT to provide estimates of ambient concentrations of air pollutants: air quality monitoring data and the Hierarchical Bayesian-derived air quality estimate, which is a statistical 'combination' of air quality monitor data and air quality modeling estimates.

Goal	Status
(1) Air data sets and metadata required for air quality indicators are available to EPHT state Grantees.	AQS data is available through state agencies and EPA's AirData and AirExplorer. EPA and CDC developed an interagency agreement, where EPA provides air quality data along with HBM modeling data, associated metadata, and technical reports that are delivered to CDC.
(2) Estimate the linkage or association of $PM_{2.5}$ and ozone on health to: A. Identify populations that may have higher risk of adverse health effects due to $PM_{2.5}$ and ozone, B. Generate hypothesis for further research, and C. Provide information to support prevention and pollution control strategies.	Regular discussions have been held on health-air linked indicators and CDC/HEI/EPA convened a workshop in January 2008. CDC has collaborated on a health impact assessment (HIA) with Emory University, EPA and state grantees that can be used to facilitate greater understanding of these linkages.
(3) Produce and disseminate basic indicators and other findings in electronic and print formats to provide the public, environmental health professionals, and policymakers, with current and easy-to-use information about air pollution and the impact on public health.	Templates and "how to" guides for $PM_{2.5}$ and ozone have been developed for routine indicators. Calculation techniques and presentations for the indicators have been developed.

Table 2-3. Public Health Surveillance Goals and Current Results

Ozone (daily 8-hr period with maximum concentration—ppm—by Federal Reference Method (FRM))
Number of days with maximum ozone concentration over the NAAQS (or other relevant benchmarks (by county and MSA)
Number of person-days with maximum 8-hr average ozone concentration over the NAAQS & other relevant benchmarks (by county and MSA)
$PM_{2.5}$ (daily 24-hr integrated samples by FRM)
Average ambient concentrations of particulate matter (< 2.5 microns in diameter) and compared to annual $PM_{2.5}$ NAAQS (by state).
% population exceeding annual $PM_{2.5}$ NAAQS (by state).
% of days with $PM_{2.5}$ concentration over the daily NAAQS (or other relevant benchmarks (by county and MSA)
Number of person-days with $PM_{2.5}$ concentration over the daily NAAQS & other relevant benchmarks (by county and MSA)

Table 2-4. Basic Air Quality Indicators

2.3 Air Quality Indicators Developed for the EPHT Network

Air quality indicators have been developed for use in the Environmental Public Health Tracking Network (EPHT). The approach divides "indicators" into two categories. First, basic air quality measures were developed to compare air quality levels over space and time within a public health context (e.g., using the NAAQS as a benchmark). Next, indicators were developed that mathematically link air quality data to public health tracking data (e.g., daily $PM_{2.5}$ levels and hospitalization data for acute myocardial infarction). Table 2-3 and Table 2-4 describe the issues impacting calculation of basic air quality indicators.

2.3.1 Rationale for the Air Quality Indicators

The CDC EPHT Network is initially focusing on ozone and $PM_{2.5}$. These air quality indicators are based mainly around the NAAQS health findings and program-based measures (measurement, data and analysis methodologies). The indicators will allow comparisons across space and time for EPHT actions. They are in the context of health-based benchmarks. By bringing population into the measures, they roughly distinguish between potential exposures (at broad scale).

2.3.2 Air Quality Data Sources

The air quality data will be available based on the state/federal air program's data collection and processing. Air quality data management (EPA's Air Quality System—AQS) and delivery systems (AirData and Air Explorer) were used in the PHASE project as the pilot test for air quality indicators. The AirExplorer functionality is now fully integrated into the AirData system, and AirExplorer is no longer a stand-alone system/application.

2.3.3 Use of Air Quality Indicators for Public Health Practice

The basic indicators will be used to inform policymakers and the public regarding the degree of hazard within a state and across states (national). For example, the number of days per year that ozone is above the NAAQS can be used to communicate to sensitive populations (such as asthmatics) the number of days that they may be exposed to unhealthy levels of ozone. This is the same level used in the Air Quality Alerts that inform these sensitive populations when and how to reduce their exposure. These indicators, however, are not a surrogate measure of exposure and therefore will not be linked with health data.

3.0 Emissions Data

3.1 Introduction to the 2007 Emissions Data Development

The U.S. EPA has developed a 2005-based air quality modeling platform for emissions data. Version 4 of the 2005 platform (i.e., 2005v4) was used to develop the year 2007 emission data for this project, where there was not 2007-specific data available. This section is a summary of the emissions inventory and emissions modeling for Criteria Air Pollutants (CAPs), and describes the approach and data used to produce emissions inputs to the air quality model. The air quality modeling, meteorological inputs and boundary conditions are described in a separate section. A complete description of the 2005v4 Platform is available in "Technical Support Document: Preparation of Emissions Inventories for the Version 4, 2005-based Platform, U.S. EPA, Research Triangle Park, NC 27711, July 2010" (available from http://www.epa.gov/ttn/chief/emch/index.html#2005).

The Community Multiscale Air Quality (CMAQ) model (http://www.epa.gov/AMD/CMAQ/) is one of the air quality models supported by the 2005v4 platform for the purposes of modeling ozone (O_3) and particulate matter (PM). The version of CMAQ used for this study requires hourly and gridded emissions of species from the following inventory pollutants: carbon monoxide (CO),nitrogen oxides (NO_X), volatile organic compounds (VOC), sulfur dioxide (SO_2), ammonia (NH_3), particulate matter less than or equal to 10 microns (PM_{10}), and individual component species for particulate matter less than or equal to 2.5 microns ($PM_{2.5}$). In addition, the CMAQ CB05 with chlorine chemistry, which is part of the "base" version of CMAQ, allows explicit treatment of the following substances, Benzene, Acetaldehyde, Formaldehyde, and Methanol (BAFM), and includes anthropogenic Hazardous Air Pollutant (HAP) emissions ofHCl and Cl. Readers may note that the version of CMAQ targeted by the 2005v4 platform does not support Hg, but other versions of the modeling platform do support Hg.

The effort to create the 2007 emission inputs for this study included development of emission inventories for a 2007 model evaluation case and application of the emissions modeling tools to convert the inventories into the format and resolution needed by CMAQ. The 2007 evaluation case uses 2007-specific fire emissions and 2007-specific continuous emission monitoring (CEM) data for electric generating units (EGUs).

The primary emissions modeling tool used to create the CMAQ model-ready emissions was the Sparse Matrix Operator Kernel Emissions (SMOKE) modeling system. SMOKE version 2.6 was used to create emissions files for a 12-km national grid. Electronic copies of some of the data used with SMOKE for the criteria air pollutants (CAP) 2005v4 Platform are available at the emissions modeling clearinghouse, http://www.epa.gov/ttn/chief/emch/, under the section entitled "CAP BAFM 2005-Based Platform, Version 4."

This summary contains two additional sections. Section 3.2 describes the inventories input to SMOKE and the ancillary files used along with the emission inventories. Section 3.3 describes the emissions modeling performed to convert the inventories into the format and resolution needed by CMAQ.

3.2 2007 Emission Inventories and Approaches

This section describes the emissions inventories created for input to SMOKE. The primary basis for the emission inputs for the 2005v4 Platform is the 2005 National Emission Inventory (NEI), Version 2. The 2005 NEI v2 includes emissions of CO, NO_x, VOC, SO_2, NH_3, PM_{10}, and $PM_{2.5}$ and hazardous air pollutants (HAPs). The 2005 platform utilizes select HAPs: the base version includes chlorine, HCl, benzene, acetaldehyde, formaldehyde, and methanol. Documentation for the 2005 NEI can be found at: http://www.epa.gov/ttn/chief/net/2005inventory.html#documentation. For inventories outside of the United States, including Canada, Mexico and offshore emissions, the latest available base year inventories were used.

The 2005 NEI includes five source sectors: a) nonpoint (formerly called "stationary area") sources; b) point sources; c) nonroad mobile sources; d) onroad mobile sources; and e) fires. The fires portion of the inventory includes emissions from wildfires and prescribed burning computed as hour-specific point sources. For purposes of preparing the CMAQ-ready emissions, the NEI is split into several additional "platform" sectors for use in emissions modeling; biogenic emissions are added along with emissions from other sources and other NEI such as the Canadian, Mexican, and offshore inventories. The significance of an emissions sector for the platform is that it is run through all of the SMOKE programs, except the final merge, independently from the other sectors. The final merge program (i.e., Mrggrid) combines the sector-specific gridded, speciated and temporalized emissions to create the CMAQ emission inputs.

Table 3-1 presents the sectors in the 2005v4 platform used to develop 2007 emissions for this project. The sector abbreviations are provided in italics; these abbreviations are used in the SMOKE modeling scripts and inventory file names and throughout the remainder of this section. Annual 2007 emission summaries for the U.S. anthropogenic sectors are shown in Table 3-2 (i.e., excluding biogenic emissions). Table 3-3 provides a summary of emissions for the anthropogenic sectors containing Canadian, Mexican and offshore sources.

2005v4 Platform Sector	2005 NEI Sector	Description and resolution of the data input to SMOKE
IPM sector: *ptipm*	Point	2005v2 NEI point source EGUs mapped to the Integrated Planning Model (IPM) model using year 2007 continuous emission monitoring (CEM) NOX and SO_2 emissions from the National Electric Energy Database System (NEEDS, 2006 version 3.02) database. Hourly files for CEM sources are included for the 2007 evaluation case used for this project. Day-specific emissions for non-CEM sources are year 2005 NEI-based estimates and were created for input into SMOKE.
Non-IPM sector: *ptnonipm*	Point	Year 2005 emissions for all 2005v2 NEI point source records not matched to the ptipm sector, annual resolution. Includes all aircraft emissions.
Point source fire sector: *ptfire*	Fires	Point source day-specific wildfires and prescribed fires for 2007.
Agricultural sector: ag	Nonpoint	Primarily 2002 NEI nonpoint NH_3 emissions from livestock and fertilizer application, county and annual resolution.
Area fugitive dust sector: *afdust*	Nonpoint	Primarily 2002 NEI nonpoint PM_{10} and $PM_{2.5}$ from fugitive dust sources (e.g., building construction, road construction, paved roads, unpaved roads, agricultural dust), county/annual resolution.
Remaining nonpoint sector: *nonpt*	Nonpoint	Primarily 2002 NEI nonpoint sources not otherwise included in other SMOKE sectors, county and annual resolution. Also includes updated Residential Wood Combustion emissions and year 2005 non-California Western Regional Air Partnership (WRAP) oil and gas "Phase II" inventory.
Nonroad sector: *nonroad*	Mobile: Nonroad	Year 2007 monthly nonroad emissions from the National Mobile Inventory Model (NMIM) using NONROAD2005 version nr05c-BondBase for all states except California. Monthly emissions for California created from annual emissions submitted by the California Air Resources Board (CARB) for the 2005v2 NEI linearly-interpolated with year 2009 emissions to create year 2007.
locomotive, and non-C3 commercial marine: *alm_no_c3*	Mobile: Nonroad	Year 2002 non-rail maintenance locomotives, and category 1 and category 2 commercial marine vessel (CMV) emissions sources, county and annual resolution. Unlike prior platforms, aircraft emissions are now included in the ptnonipm sector and category 3 CMV emissions are now contained in the seca_c3 sector
C3 commercial marine: *seca_c3*	Mobile : Nonroad	Annual point source formatted year 2007 category 3 (C3) CMV emissions, developed for the EPA rule called "Control of Emissions from New Marine Compression-Ignition Engines at or Above 30 Liters per Cylinder", usually described as the Area (ECA) study, originally called SO2 ("S") ECA.
Onroad California, NMIM-based, and MOVES sources not subject to temperature adjustments: *on_noadj*	Mobile: onroad	Year 2007 emissions consisting of two, monthly, county-level components: 1. MOVES2010-based (December 2009) except for California and gasoline exhaust PM. 2. California onroad, created using annual EMFAC-based emissions submitted by CARB for the 2005v2 NEI, linearly-interpolated with year 2009 EMFAC-based submissions.
Onroad cold-start gasoline exhaust mode vehicle from MOVES subject to temperature adjustments: *on_moves_startpm*	Mobile: onroad	Year 2007 monthly, county-level MOVES2010-based onroad gasoline emissions subject to temperature adjustments. Limited to exhaust mode only for PM species. California emissions not included. This sector is limited to cold start mode emissions that contain different temperature adjustment curves from running exhaust (see on_moves_runpm sector).
Onroad running gasoline exhaust mode vehicle from MOVES subject to temperature adjustments: *on_moves_runpm*	Mobile: onroad	Year 2007 monthly, county-level MOVES2010-based onroad gasoline emissions subject to temperature adjustments. Limited to exhaust mode only for PM species. California emissions not included. This sector is limited to running mode emissions that contain different temperature adjustment curves from cold start exhaust (see on_moves_startpm sector).
Biogenic: *beis*	N/A	Hour-specific, grid cell-specific emissions generated from the BEIS3.14 model -includes emissions in Canada and Mexico.
Other point sources not from the NEI: *othpt*	N/A	Point sources from Canada's 2006 inventory and Mexico's Phase III 1999 inventory, annual resolution. Also includes annual U.S. offshore oil 2005v2 NEI point source emissions.

2005v4 Platform Sector	2005 NEI Sector	Description and resolution of the data input to SMOKE
Other nonpoint and nonroad not from the NEI: *othar*	N/A	Annual year 2006 Canada (province resolution) and year 1999 Mexico Phase III (municipio resolution) nonpoint and nonroad mobile inventories, annual resolution.
Other onroad sources not from the NEI: *othon*	N/A	Year 2006 Canada (province resolution) and year 1999 Mexico Phase III (municipio resolution) onroad mobile inventories, annual resolution.

Table 3-3. 2007 Non-US Emissions by Sector (tons/yr for Canada, Mexico, Offshore)

3.2.1 Point Sources (ptipm and ptnonipm)

Point sources are sources of emissions for which specific geographic coordinates (e.g., latitude/longitude) are specified, as in the case of an individual facility. A facility may have multiple emission points, which may be characterized as units such as boilers, reactors, spray booths, kilns, etc. A unit may have multiple processes (e.g., a boiler that sometimes burns residual oil and sometimes burns natural gas). Note that this section describes only contiguous U.S. NEI point sources. The offshore oil platform (othpt sector) and category 3 CMV emissions (seca_c3 sector) are point source formatted inventories, but they are discussed later in this section.

After removing offshore oil platforms into the othpt sector, two platform sectors were created from the remaining 2005 point source NEI, v2 for input into SMOKE: the Integrated Planning Model (IPM) sector (ptipm) and the non-IPM sector (ptnonipm). This split facilitates the use of different SMOKE temporal processing and future year projection techniques for these sectors. The inventory pollutants processed through SMOKE for both ptipm and ptnonipm sectors were: CO, NO_X, VOC, SO_2, NH_3, PM_{10}, $PM_{2.5}$ and the following HAPs: HCl and Cl. BAFM from these sectors was not used and instead the VOC was speciated without any integration of VOC HAP (integration is discussed in detail in Section 3.3.4).

The ptnonipm emissions were provided to SMOKE as annual emissions. In the 2007 model evaluation case used in this study, for ptipm sector sources with CEM data that could be matched to the NEI, 2007 hourly SO_2 and NO_X emissions were used alongside annual emissions of all other pollutants. The hourly data also contained heat input, which was used to allocate the annual emissions to hourly values. For the non-CEM sources, daily emissions were created, and state-specific diurnal profiles were applied to create hourly emissions.

Full documentation for the development of the 2005 point source NEI, v2, is at:

http://www.epa.gov/ttn/chief/net/2005inventory.html#documentation. A summary of this documentation follows:

1. Electric generating unit (EGU) emissions are obtained from emissions and heat input from EPA'S Acid Rain Program. The following approach applied to units in the 2002 NEI that matched to 2005 CEMS units. For pollutants covered by the CEMS, the 2007 CEMS data were used. For CEMS units with pollutants not covered by CEMS (e.g., VOC, $PM_{2.5}$, HCl) unit specific ratios of 2007 to 2005 heat input were applied to 2005 NEI v2 emissions to obtain 2007 estimates.
2. Non-EGU Stationary Source enhancements focused on improving the following sectors:
   a. HAP data received from States and industry to support the MACT program, including the recent Risk and Technology Review rulemaking
   b. 2005 State, local, and tribal data submitted to EPA under the Consolidated Emissions Reporting Rule (CERR)
   c. HAP data from Toxic Release Inventory (TRI) for missing facilities and pollutants
   d. Off-shore platform data from Mineral Management Services (MMS)

The changes made to the 2005 NEI point sources prior to modeling are as follows:

- The tribal data, which do not use state/county Federal Information Processing Standards (FIPS) codes in the NEI, but rather use the tribal code, were assigned a state/county FIPS code of 88XXX, where XXX is the 3-digit tribal code in the NEI. This change was made because SMOKE requires the state/county FIPS code.
- Stack parameters for some point sources were defaulted when modeling in SMOKE. SMOKE uses an ancillary file, called the PSTK file, which provides default stack parameters by Source Classification Code (SCC) to either 'gap fill' stack parameters if they are missing in the NEI or to correct stack parameters if they are outside the ranges specified in SMOKE for acceptable values. The SMOKE PSTK file is contained in the ancillary file directory of the 2005v4 website.
- A transport fraction was applied to all SCCs that were identified as PM fugitive dust, to prevent the overestimation of fugitive dust impacts in the grid modeling.

3.2.1.1 IPM Sector (ptipm)

The ptipm sector contains emissions from EGUs in the 2005 NEI version 2 point inventory that could be matched to the units found in the 2006 NEEDS database, version 3.02 (http://www.epa.gov/airmarkets/progsregs/epa-ipm/index.html), which is used by the IPM, version 3.02. The IPM model provides future year emission inventories for the universe of EGUs contained in the NEEDS database. As described below, this matching was done in order to (1) provide consistency between the 2005 EGU sources and future year EGU emissions for sources which are forecasted by IPM and (2) avoid double counting in projecting point source emissions.

The 2005 NEI point source inventory contains emissions estimates for both EGU and non-EGU sources. The IPM is used to predict the future year emissions for the EGU sources. The remaining non-EGU point sources are projected by applying projection and control factors to the base year emissions. It was therefore necessary to identify and separate into two sectors: (1) all sources that are projected via the IPM and (2) those that are not. This procedure prevents double-counting or dropping significant emissions when creating the future-year emissions. The matching process relies on imperfect data; consequently, a small degree of dropped and/or double-counted emissions occurred for sources that we could not match. We believe that the unmatched units are small emissions sources because we have reviewed both the NEI and the NEEDS database to ensure that all significant EGUs have been captured in the matching process.

The methodology that follows describes how the point inventory was split into the ptipm and ptnonipm sectors. The

approach started with the splits identified for the 2002 NEI (step 1) and then included additional steps to apply these to the 2005 NEI.

The methodology used to split the EGU emission sources from the non-EGU emission sources was implemented as follows:

Step 1: Obtain facilities and units identified as EGUs from the 2002 NEI

2005 NEI units were identified as IPM units using the 2006 NEEDS 3.0 database. This methodology is described in the 200 Platform documentation previously referenced. Since some source identifiers are held constant between the 2002 and 2005 NEI, particularly "NEI Unique ID", it was easier to compare the two inventories to ensure that improvements were made in the 2005 matching rather than having inadvertent omissions.

Step 2: Create the 2005 NEI v2 point modeling inventory from the 2005v2 NEI and impacts on EGU matching

The published 2005 NEI v2 point inventory was enhanced to improve the ptipm and ptnonipm splits and make other updates. What follows are the issues and their resolution. These changes represent differences between the published 2005 v2 NEI and what was used for modeling.

1. Facilities with added HAP emissions records that were clearly EGUs, but had not been flagged as "IPM" sources were identified. These facilities had facility identifiers (i.e., plant IDs) beginning with "EGU". It was further confirmed that these records were EGU emissions; and therefore, these units were moved to the ptipm sector.
2. One additional unit with HAP emissions records not flagged as an EGU was found, after confirming that representing emissions were from a facility for which CAP records were identified as ptipm sector records. This unit (South Mississippi Electric Power, plantid = 2807300021, unitid = 012, NEI_UNIQUE_ID=NEI409) was moved into the ptipm inventory.
3. Several facilities and units closed between 2002 and 2005 and had not initially been removed in the development of the 2005v2 NEI; these were removed based on a list from the NEI developers.
4. Inspection of CEM and 2005 NEI v2 point inventory revealed some duplication of sources with state and non-state reported data. This can occur because EPA created the EGU records in the 2005 NEI, but the states sometimes still submitted these emissions records. These duplicates were removed.
5. ORIS facility and boiler codes (used to match to the CEM hourly data) were unintentionally dropped between a preliminary and final 2005 NEI v2 point dataset. These ORIS facility and boiler codes were repopulated based on available data.

Another reason the ptipm sources were separated from the other sources was due to the difference in the temporal resolution of the data input to SMOKE. The ptipm sector uses the available hourly CEM data via a method first implemented in the 2002 platform that was also used for the 2005 platform. For sources with CEMs, the actual year 2007 hourly CEM data were used. The hourly CEM data were obtained from the CAMD Data and Maps website[3]. The SMOKE modeling system matches the ORIS Facility and Boiler IDs in the NEI SMOKE-ready file to the same fields in the CEM data. This allowed us to use the hourly SO_2 and NO_X CEM emissions directly from the CEM data file. The heat input from the hourly CEM data was used to allocate the NEI annual values for all other pollutants from CEM sources, because hourly data for these other pollutants are not available with the hourly CEM data.

For sources not matching the CEM data ("non-CEM" sources), daily emissions were computed from the NEI annual emissions using a structured query language (SQL) program and state-average CEM data. To allocate annual emissions to each month, state-specific, three-year averages of 2006-2008 CEM data were created. These average annual-to-month factors were assigned to non-CEM sources by state. To allocate the monthly emissions to each day, the 2007 CEM data were used to compute state-specific month-to-day factors, which were then averaged across all units in each state. The resulting daily emissions were input into SMOKE. The daily-to-hourly allocation was performed in SMOKE using diurnal profiles. The development of these diurnal ptipm-specific profiles, considered ancillary data for SMOKE, is described in a later section.

3.2.1.2 Non-IPM Sector (ptnonipm)

The non-IPM (ptnonipm) sector contains all 2005 NEI v2 point sources not included in the IPM (ptipm) sector[4]. The ptnonipm sector contains fugitive dust PM emissions from vehicular traffic on paved or unpaved roads at industrial facilities or coal handling at coal mines. Prior to input to SMOKE, the fugitive dust PM emissions were reduced to estimate the emissions that remain aloft by applying county-specific fugitive dust transportable fraction factors. This is discussed further in Section 3.2.2.1.

For some geographic areas, some of the sources in the ptnonipm sector belong to source categories that are contained in other sectors. This occurs in the inventory when states, tribes or local programs report certain inventory emissions as point sources because they have specific geographic coordinates for these sources. They may use point source SCCs (8-digit) or non-point, onroad or nonroad (10-digit) SCCs. In the 2005 NEI, examples of these types of sources include: aircraft emissions in all states, waste disposal emissions in several states, firefighting training in New Mexico, several industrial processes and solvent utilization sources in North Carolina and Tennessee, livestock (i.e., animal husbandry) in primarily Kansas and Minnesota,

[3] http://camddataandmaps.epa.gov/gdm/index.cfm?fuseaction=emissions.wizard

[4] Except for the offshore oil and day-specific point source fire emissions data which are included in separate sectors, as discussed in sections 2.6 and 2.3.1, respectively.

and petroleum product working losses.

The most significant changes made to the ptnonipm emissions involved moving some HAP records that should have been flagged as IPM into the ptipm sector. The other modifications are listed here and represent differences between the published 2005 NEI v2 and the 2005 inventory used for modeling:

1. Removed duplicate annual records (not sub-annual, non-repeating records).
2. Removed a source with a state/county FIPS code of 30777; the "777" county FIPS represents portable facilities that move across counties, but is not currently a valid state/county FIPS code in the SMOKE ancillary file "COSTCY". This Montana FIPS code was located in northern Wyoming and contained very small emissions.
3. Dropped sources with coordinates located well into the oceans or lakes.
4. Fixed the coordinates for several larger sources that had a state/county FIPS code mismatch with their inventory coordinates greater than 10 km and emissions greater than 10 tons per year of either NO_X, VOC, SO_2, or 5 tons/yr of $PM_{2.5}$. These corrections were limited to a small number of plants in Arizona, Indiana, Kentucky, Ohio, and Virginia.

3.2.2 Nonpoint Sources (afdust, ag, nonpt)

The nonpoint portion of the 2005 NEI v2 generally did not include updated emissions from the values used in the 2002 NEI, and this modeling platform took a similar approach. Consequently, several sectors were created from the 2002 nonpoint NEI prior to modeling. The nonpoint tribal-submitted emissions were removed to prevent possible double counting with the county-level emissions. Because the tribal nonpoint emissions are small, these omissions should not impact results at the 12-km scale used for modeling. This omission also eliminated the need to develop costly spatial surrogate data to allocate tribal data to grid cells during the SMOKE processing. The documentation for the nonpoint sector of the 2005 NEI is available at: http://www.epa.gov/ttn/chief/net/2005inventory.html

In the rest of this section, each of the platform sectors into which the 2005 nonpoint NEI was divided is described, as are the changes made to these data. See the 2002 platform documentation for sectors that did not change

3.2.2.1 Area Fugitive Dust Sector (afdust)

The area-source fugitive dust (afdust) sector contains PM_{10} and $PM_{2.5}$ emission estimates for 2002 NEI nonpoint SCCs identified by EPA staff as dust sources. This sector is separated from other nonpoint sectors to make it easier to apply a "transport fraction," that reduces emissions to reflect observed diminished transport from these sources at the scale of our modeling. Application of the transport fraction prevents the overestimation of fugitive dust impacts in the grid modeling as compared to ambient samples. Categories included in this sector are paved roads, unpaved roads and airstrips, construction (residential, industrial, road and total), agriculture production and all of the mining 10-digit SCCs beginning with the digits "2325." It does not include fugitive dust from grain elevators because these are elevated point sources.

The afdust sector was created from the 2002 NEI based on SCCs and pollutant codes (i.e., PM_{10} and $PM_{2.5}$) that are considered "fugitive". A complete list of all possible fugitive dust SCCs (including both 8-digit point source SCCs and 10-digit nonpoint SCCs) is provided at: http://www.epa.gov/ttn/chief/emch/dustfractions/tf_scc_list2002nei_v2.xls. However, not all of the SCCs in this file are present in the 2002 NEI.

Our approach was to apply the transportable fractions by county such that all afdust SCCs in the same county receive the same factor. The approach used to calculate the county-specific transportable fractions is based on land use data and is described by: http://www.epa.gov/ttn/chief/emch/dustfractions/transportable_fraction_080305_rev.pdf

As the paper describing the approach mentions, a limitation of the transportable fraction approach is the lack of monthly variability, which would be expected due to seasonal changes in vegetative cover. Further, the variability due to soil moisture, precipitation, and wind speeds is not accounted for by the methodology. An electronic version of the county-level transport fractions can be found at: http://www.epa.gov/ttn/chief/emch/dustfractions/transportfractions052506rev.xls

3.2.2.2 Agricultural Ammonia Sector (ag)

The agricultural NH_3 "ag" sector comprises livestock and agricultural fertilizer application emissions from the nonpoint sector of the 2002 NEI. This sector is unchanged in the 2005 platform. In building this sector, livestock and fertilizer emissions were extracted based on the SCC. The "ag" sector includes all of the NH_3 emissions from fertilizer from the NEI. However, the "ag" sector does include all of the livestock ammonia emissions, as there are also significant NH_3 emissions from livestock in the point source inventory. Most of the point source livestock NH_3 emissions were reported by the states of Kansas and Minnesota. For these two states, farms with animal operations were provided as point sources.[5]

The "ag" sector includes all of the NH_3 emissions from fertilizer from the NEI. However, the "ag" sector does not include all of the livestock ammonia emissions, as there are also significant NH_3 emissions from livestock in the point source inventory retained from the 2002 NEI. Note that in these cases, emissions were not also in the nonpoint inventory for counties for which they were in the point source inventory; therefore no double counting occurred. Most of the point source livestock NH_3 emissions were reported by the states of Kansas and Minnesota. For these two states, farms with animal operations were provided as point sources using the following SCCs[6]:

[5] These point source emissions are also identified by the segment ID, which is one of the following: "SWINE," "CATTLE," "DAIRY," or "PLTRY."

[6] These point source emissions are also identified by the segment ID, which is one of the following: "SWINE", "CATTLE", "DAIRY", or "PLTRY".

- 30202101: Industrial Processes; Food and Agriculture; Eggs and Poultry Production; Manure Handling: Dry
- 30203099: Industrial Processes; Food and Agriculture; Dairy Products; Other Not Classified

There are also livestock NH_3 emissions in the point source inventory with SCCs of 39999999 (Industrial Processes; Miscellaneous Manufacturing Industries; Miscellaneous Industrial Processes; Other Not Classified) and 30288801 (Industrial Processes; Food and Agriculture; Fugitive Emissions; Specify in Comments Field). These sources were identified as livestock NH_3 point sources based on their facility name. The reason the livestock NH_3 emissions in the ptnonipm sector had to be identified was to properly implement the emission projection techniques for livestock sources in future years. The projection techniques cover all livestock sources, including those in the ag and ptnonipm sectors.

3.2.2.3 Other Nonpoint Sources (nonpt)

Nonpoint sources that were not subdivided into the afdust, ag or nonpt sectors were assigned to the "nonpt" sector. In preparing the nonpt sector, catastrophic releases were excluded since these emissions were dominated by tire burning, which is an episodic, location-specific emissions category. Tire burning accounts for significant emissions of particulate matter in some parts of the country. Because such sources are reported by a very small number of states, and are inventoried as county annual totals without the information in the NEI to temporally and spatially allocate the emissions to the time and location where the event occurred, catastrophic releases were excluded.

The nonpt sector includes emission estimates for Portable Fuel Containers (PFCs), also known as "gas cans." Inventories for PFCs were recently developed for EPA's Mobile Source Air Toxics (MSAT) rule and were incorporated into the 2002 NEI v3. The PFC inventory consists of five distinct sources of PFC emissions, further distinguished by residential or commercial use. The five sources are: (1) displacement of the vapor within the can; (2) spillage of gasoline while filling the can; (3) spillage of gasoline during transport; (4) emissions due to evaporation (i.e., diurnal emissions); and (5) emissions due to permeation. Note that spillage and vapor displacement associated with using PFCs to refuel nonroad equipment are included in the nonroad inventory.

Statewide total annual VOC inventories were allocated to counties using county-level fuel consumption ratios from the NONROAD model. Of note from this documentation, the developers derived the 2002 PFC inventory by linearly interpolating inventories developed for 1999 and 2010.

3.2.4 Day-Specific Point Source Fires (ptfire)

Wildfire and prescribed burning emissions are contained in the ptfire sector. The ptfire sector has emissions provided at geographic coordinates (point locations) and has daily emissions values.

For the 2005 Platform, the following SCCs from the 2005 NEI are considered "fires" (note that the actual SCC description includes "Miscellaneous Area Sources" as the first tier level description):

- 2810001000: Miscellaneous Area Sources; Other Combustion; Forest Wildfires; Total
- 2810015000: Miscellaneous Area Sources; Other Combustion; Prescribed Burning for Forest Management; Total
- 2810005000: Miscellaneous Area Sources; Managed Burning, Slash (Logging Debris); Total

The ptfire sector for the 2005 Platform excludes agricultural burning and other open burning sources, which are included in the nonpt sector. The agricultural burning and other open burning sources are in the nonpt sector because these categories were not factored into the development of the ptfire sector. Additionally, their year-to-year impacts are not as variable as wildfires and non-agricultural prescribed/ managed burns.

The ptfire sector includes wildfire and prescribed[7] burning emissions occurring in 2007, which were used for the 2007 model evaluation case. This sector includes emissions for all 2007 wildfires and many prescribed burns with daily estimates of each fire's emissions. It includes a satellite derived latitude/longitude of the fire's origin and other parameters associated with the emissions such as acres burned and fuel load, which allow estimation of plume rise. Note that Agricultural Burning is not included in the ptfire sector as it is included in the nonpt sector.

The SCCs in the ptfire sector are the following:

- 2810001000: Miscellaneous Area Sources; Other Combustion; Forest Wildfires; Total
- 2810005000: Miscellaneous Area Sources; Other Combustion; Managed Burning, Slash (Logging Debris);Total

The point source day-specific emission estimates for 2007 fires rely on Sonoma Technology, Inc.'s Satellite Mapping Automated Reanalysis Tool for Fire Incident Reconciliation (SMARTFIRE) system (Sullivan, et al., 2008). Figure 3-1 shows a functional diagram of the SMARTFIRE process. SMARTFIRE involves the use the National Oceanic and Atmospheric Administration's (NOAA's) Hazard Mapping System (HMS) fire location information as input combined with CONSUMEv3.0, a computer program designed to predict emissions, fuel consumption, and heat release from naturally burning fuels such as wood (Joint Fire Science Program, 2009), and the Fuel Characteristic Classification System (FCCS) fuel-loading database to estimate fire emissions from wildfires and prescribed burns on a daily basis.

The method involves the reconciliation of ICS-209 reports (Incident Status Summary Reports) with satellite-based fire detections to determine spatial and temporal information about the fires. The ICS-209 reports for each large wildfire

[7] For purposes of this document prescribed burning also includes managed burning, i.e., "Other Combustion; Managed Burning, Slash (Logging Debris)"

are created daily to enable fire incident commanders to track the status and resources assigned to each large fire (100 acre timber fire or 300 acre rangeland fire). The SMARTFIRE system of reconciliation with ICS-209 reports is described in an Air and Waste Management Association report (Raffuse, et al., 2007). Once the fire reconciliation process is completed, the emissions are calculated using the U.S. Forest Service's CONSUMEv3.0 fuel consumption model and the FCCS fuel-loading database in the Bluesky Framework (Ottmar, et al., 2007).

The detection of fires with this method is satellite-based. Note that the distinction between wildfire and prescribed burn is not as precise as with ground-based methods. The fire size was based on the number of satellite pixels and a nominal fire size of 100 acres/pixel was assumed for a significant number of fire detections when the first detections were not matched to ICS 209 reports, so the fire size information is not as precise as ground-based methods. Because the HMS satellite product from NOAA is based on daily detections, the emission inventory represents a time-integrated emission estimate. For example, a large smoldering fire will show up

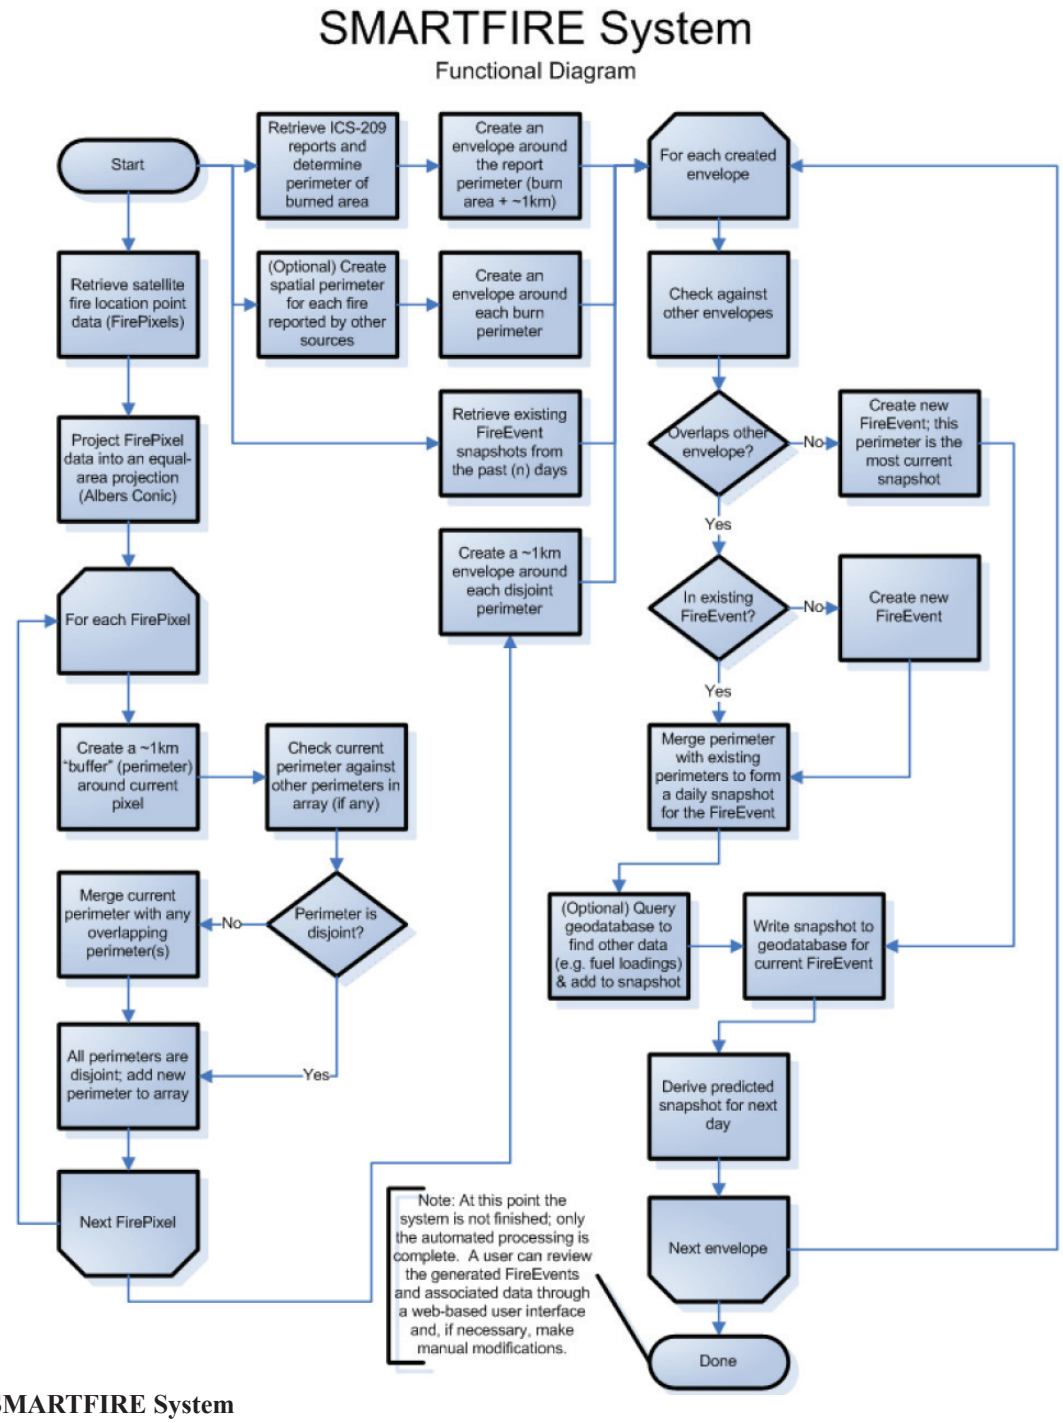

Figure 3-1. SMARTFIRE System

on satellite for many days and would count as acres burned on a daily basis whereas a ground-based method would count the area burned only once even it burns over many days. Additional references for this method are provided in McKenzie, et al., 2007; Ottmar et al., 2003; Ottmar et al., 2006; and Anderson et al., 2004.

The SMOKE-ready "ORL" inventory files created from the raw daily fires contain both CAPs and HAPs. The HAPs were generated using the same emission factors as were used in the 2002 Platform and described in Section 2.3 of the CAP and HAP 2002-Based Platform, Version 3 (ftp://ftp.epa.gov/EmisInventory/2002v3CAPHAP/documentation). The BAFM HAP emissions from the inventory were obtained using VOC speciation profiles (i.e., a "no-integrate noHAP" use case).

3.2.5 Biogenic Sources (beis)

For CMAQ, biogenic emissions were computed based on 2005 meteorology data using the BEIS3.14 model from SMOKE. The 2002 platform used the BEIS3.13 model; otherwise, all underlying land use data and parameters are unchanged for the 2005 platform.

The BEIS3.14 model creates gridded, hourly, model-species emissions from vegetation and soils. It estimates CO, VOC, and NO_X emissions for the U.S., Mexico, and Canada. The BEIS3.14 model is described further in: http://www.cmascenter.org/conference/2008/slides/pouliot_tale_two_cmas08.ppt.

The inputs to BEIS include:

- Temperature data at 2 meters which were obtained from the CMAQ meteorological input files,
- Land-use data from the Biogenic Emissions Landuse Database, version 3 (BELD3). BELD3 data provides data on the 230 vegetation classes at 1-km resolution over most of North America, which is the same land-use data were used for the 2002 platform.

3.2.6 2005 Mobile Sources (on_noadj, on_moves_runpm, on_moves_startpm, nonroad, alm_no_c3, seca_c3)

The 2005v4 platform onroad emissions are broken out into three sectors: (1) "on_moves_startpm"; (2) "on_moves_runpm"; and (3) "on_noadj". The aircraft, locomotive, and commercial marine emissions are divided into two nonroad sectors: "alm_no_c3" and "seca_c3", and as previously mentioned, the aircraft emissions are now in the nonEGU point inventory.

While the previous EPA platforms used NMIM for the onroad and nonroad sectors[8], some of the onroad emissions in the 2005 platform were based on an initial version[9] of the MOVES2010 model run for the year 2007. This MOVES2010 model was used to make sure to include the exhaust mode $PM_{2.5}$ emissions from onroad gasoline vehicles, including temperature effects that are much larger than were found in previous versions of onroad $PM_{2.5}$. The onroad gasoline emissions are based on MOVES2010 for the pollutants listed in Table 3-4. MOVES2010 was used to create 2007 emissions by state and month and these emissions were then allocated to counties based on 2005 NMIM-based county-level data. The reason for the state resolution was due to (a) run time issues that made a county run done for the nation infeasible in the timeframe required and (b) uncompleted efforts to create a national database of county-specific inputs to MOVES2010. The emissions that did not come from the MOVES2010 model were obtained from the 2005 NMIM runs, which are consistent with the 2005 NEI v2

Included in the 2005 CAP-BAFM Platform
$PM_{2.5}$; exhaust, partially speciated[2]
PM_{10}; total exhaust
$PM_{2.5}$ and PM_{10} brake and tire wear, not speciated
VOC; except refueling
CO
NO_X
SO_2
Benzene; except refueling
Formaldehyde
Acetaldehyde

Table 3-4. Pollutants covered by the MOVES2010 model in the 2005 Platform[1]

[1] MOVES2010 data were used only for onroad gasoline vehicles with the exception of motorcycles. MOVES2010 data were not used for any California onroad emissions

[2] Exhaust mode $PM_{2.5}$ species from MOVES consist of: PEC, PSO_4 and the difference between $PM_{2.5}$ and PEC (named as "PM25OC"). Brake wear and tire wear $PM_{2.5}$ emissions were not available from draft MOVES.

For onroad mobile emissions in California, year 2007 emissions were generated by linearly interpolating year 2005 and year 2009 EMFAC-based emissions. For nonroad mobile emissions in California, year 2007 emissions were generated by linearly interpolating year 2005 and year 2009 OFFROAD model-based emissions. The 2005 v2 NEI contains onroad and nonroad mobile emissions generated using NMIM (EPA, 2005b) for all of the U.S. except for California.[10] NMIM data was used for some of the nonroad mobile sources. NMIM relies on calculations from the MOBILE6 and NONROAD2005 models as described below, and in the NEI documentation. Inputs to NMIM are posted with the 2005 Emission Inventory. The direct link is: ftp://ftp.epa.gov/EmisInventory/2005_nei/mobile_sector/ncd/ncd20080522.zip.

NMIM creates the onroad and nonroad emissions on a month-specific basis that accounts for temperature, fuel types, and other variables that vary by month. Inventory

[8] Other than California which were provided by CARB and were based on the mobile models used by California, EMFAC and OFFROAD, for onroad and nonroad emissions, respectively.

[9] The version of MOVES is "MOVES2010" released in December 2009, this initial version was replaced by the publicly released MOVES2010a version in August 2010 and is available at www.epa.gov/otaq/models/moves/

[10] Although OTAQ generated emissions using NMIM for California, these were not used in the 2005 NEI version 2, but rather were replaced by state-submitted emissions.

documentation for the 2005 NEI v2 onroad and nonroad sectors is also posted with other 2005 NEI documentation; the direct link is: ftp://ftp.epa.gov/EmisInventory/2005_nei/mobile/2005_mobile_nei_version_2_report.pdf. The year 2007 NMIM nonroad emissions were generated using updated activity (fuels, vehicle population, etc) data, but are otherwise similar in methodology to those generated for the 2005 NEI.

The residual fuel commercial marine vessel (CMV), also referred to as Category 3 (C3) consists of a set of approximately 4-km resolution point source format emissions; these are now modeled separately as point sources in the "seca_c3" sector for the 2005 platform, and were projected to year 2007 using OTAQ-supplied growth factors.

The nonroad sector is the only 2002 mobile sector with U.S. emissions that was left intact in the 2005v4 platform and is still based on NMIM. For this study, NMIM was run for 2007.

With the exception of the seca_c3 point source-formatted sector, the mobile sectors are at county and SCC resolution. Tribal data from the alm_no_c3 sector have been dropped because spatial surrogate data is not available, and the emissions are small. Thus, these data were removed from the SMOKE input inventories for 2005.

All mobile sectors that have benzene, acetaldehyde, formaldehyde or methanol present in the inventory data, use these HAPs via "integration" for input into the air quality model. A few categories of nonroad sources (CNG and LPG-fueled equipment) do not have BAFM and therefore utilize the "no-integrate", "no-hap-use" case which means VOC from these sources is speciated to provide BAFM.

3.2.7 Adjustments to Onroad Mobile Source PM Emissions (on_moves_runpm, on_moves_startpm)

The on_moves_rupm and on_moves_startpm sectors contain MOVES2010 emissions for PM for non-California onroad gasoline cold-start exhaust except for motorcycles. These emissions (and the on_moves_runpm sector discussed in the next section) are processed separately from the remainder of the onroad mobile emissions because they are subject to hourly temperature adjustments, and these temperature adjustments are different for cold-start and running exhaust modes.

Temperature adjustments were applied to account for the strong sensitivity of PM exhaust emissions to temperatures below 72 ºF. Because it was not feasible to run MOVES directly for all of the gridded, hourly temperatures needed for modeling, emissions of PM exhaust at 72 ºF were created and temperature adjustments applied after the emissions were spatially and temporally allocated. The $PM_{2.5}$ adjustments were different for starting and running exhaust and applied to SMOKE gridded, hourly intermediate files using the gridded hourly temperature data also input to the CMAQ model. One result of this approach is that inventory summaries based on the raw SMOKE inputs for the on_moves_startpm and on_moves_runpm sectors will not be consistent with the final modeled emissions because they will not include the temperature adjustments. As a result, the post-processing for temperature adjustments included computing the emissions totals at state, county, and month resolution to use for summaries.

Figure 3-2 shows how PM emissions increase with colder temperatures and how start exhaust emissions increase more than running exhaust emissions.

A number of features of the MOVES output required additional processing to develop county-level monthly ORL files for SMOKE. As stated earlier, the spatial resolution of the MOVES data was at the state level and these data were allocated to county level prior to input into SMOKE. In addition, the exhaust $PM_{2.5}$ emissions from MOVES were partially speciated. To retain the speciated elemental carbon and sulfate emissions from MOVES, the speciation step that is usually done in SMOKE was performed prior to SMOKE, and it was modified to allow the temperature adjustments to be done only on the species affected by temperature. Finally, because the start emissions were broken out separately from running exhaust emissions, they were assigned to new SCCs (urban and rural parking areas) that allowed for the appropriate spatial and temporal profiles to be applied in SMOKE.

A list of the procedures performed to prepare the MOVES data for input into SMOKE is provided below.

i. State-level emissions were allocated to counties using state-county emission ratios by SCC, pollutant, and emissions mode (e.g., evaporative, exhaust) for each month. The ratios were computed using NMIM 2007 data.

ii. Start and run emissions were assigned to urban and rural SCCs based on the county-level ratio of emissions from urban versus rural local roads from the NMIM onroad gasoline data. For example, the LDGV start emissions in the state-total MOVES data (assigned SCC 2201001000) were split into urban (2201001370) and rural (2201001350) based on the ratio of LDGV urban (2201001330) and rural (2201001210) local roads.

iii. MOVES-based $PM_{2.5}$ species at 72 ºF were converted to SMOKE-ready PM species. The SMOKE-ready species are listed below and the speciation technique used to obtain the SMOKE-ready species is further discussed in Appendix B of the 2005v4 emissions modeling platform documentation.

- PEC_72: unchanged from MOVES-based PM25EC, subject to temperature adjustment below 72 ºF.

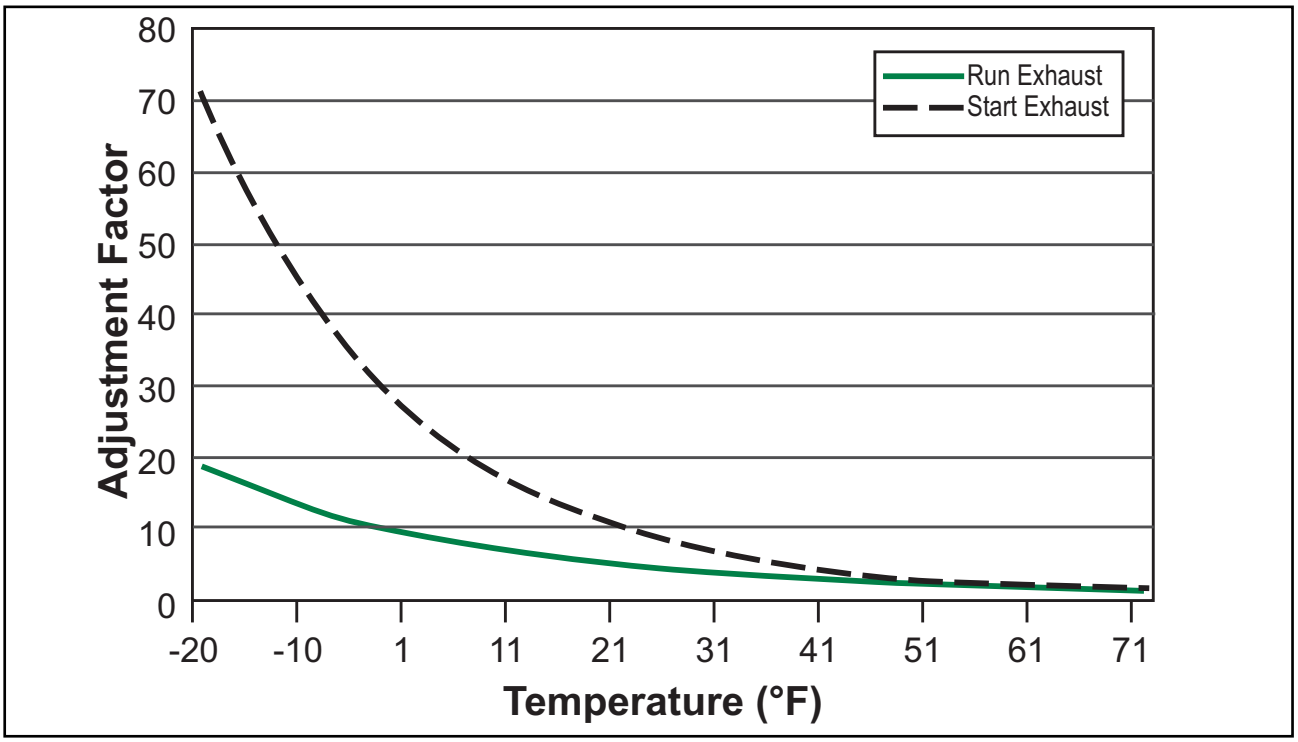

Figure 3-2. MOVES exhaust temperature adjustment functions.

- POC_72: modified MOVES-based PM25OC to remove metals, PNO3 (computed from MOVES-based PM25EC), NH_4 (computed from MOVES-based PM25SO4 and PNO3), and MOVES-based PM25SO4. Subject to temperature adjustment below 72 ºF.
- PSO_4: unchanged from MOVES-based PM25SO4, not subject to temperature adjustment.
- PNO_3: computed from MOVES-based PM25EC, not subject to temperature adjustment.
- OTHER: sum of computed metals (fraction of MOVES-based PM25EC) and NH_4 (computed from PNO3 and PSO4), not subject to temperature adjustment.
- PMFINE_72: Computed from OTHER and fraction of POC_72. Subject to temperature adjustment below 72 ºF.
- PMC_72: Computed as fraction of sum of PMFINE_72, PEC_72, POC_72, PSO4, and PNO3. Subject to temperature adjustment below 72 ºF.

The result of these preprocessing steps is that SMOKE-ready PM emissions that do not exactly match what MOVES provides. The emissions are conserved during allocation from the state to county and from the generic total "start" SCCs to the two new parking SCCs that end in "350" and "370". Primary particulate elemental carbon (PEC) and primary particulate sulfur (PSO_4) components of $PM_{2.5}$ emissions are also conserved as they are simply renamed from the MOVES specie "PM25EC". However, as seen above, POC, PNO_3, and PMFINE components involve multiplying the MOVES PM species by components of an onroad gasoline exhaust speciation profile described in Appendix B of the 2005v4 platform documentation.

3.2.8 Onroad Mobile Sources without Adjustments (on_noadj)

The on_noadj sector consists of the remaining onroad mobile emissions not covered by the on_moves_startpm and on_moves_runpm sectors. These emissions did not receive any temperature adjustments in our processing. There are four sources of data that are pre-processed to create two sets of monthly inventories for this sector.

1. MOVES-based onroad excluding gasoline exhaust PM: These are the monthly MOVES-based emissions from three MOVES inventories:
   a. Diesel Exhaust: VOC, NO_X, SO_2, $PM_{2.5}$, PM_{10}, NH_3, CO, 1,3-butadiene (106990), acetaldehyde (75070), acrolein (107028), benzene (71432), and formaldehyde (50000)
   b. Gasoline Exhaust: VOC, NO_X, SO_2, NH_3, CO, 1,3-butadiene (106990), acetaldehyde (75070), acrolein (107028), benzene (71432), and formaldehyde (50000)
   c. Evaporative: Non-refueling VOC and benzene
   d. Brake and tire wear: Total (not speciated) $PM_{2.5}$ and PM_{10} from gasoline and diesel vehicles

e. For these pollutants listed, these non-California MOVES emissions do not require the same intermediate temperature adjustments and can therefore be processed with the remaining "no adjust" onroad mobile emissions. These emissions contain both running and parking sources and are pre-processed from state-level to county-level much like the on_moves_startpm and on_moves_runpm sectors already discussed. The preprocessing for these emissions did not require species calculations because the raw MOVES emissions translated directly to SMOKE inventory species.

2. California onroad inventory: California year 2007 complete CAP/HAP onroad inventory. California monthly onroad emissions are year 2007 and are based on September 2007 California Air Resources Board (CARB) submitted 2005 and 2009 data which has been interpolated to provide 2007 values. NH_3 emissions are from NMIM runs for California. Only those HAPs that are also estimated by NMIM for nonroad mobile sources were retained; all other HAPs provided by California were dropped. The California onroad inventory does not use the SCCs for Heavy Duty Diesel Vehicles (HDDV) class 6 & 7 (2230073XXX) emissions. California does not specify road types, so NMIM California ratios were used to break out vehicle emissions to the match the more detailed NMIM level.

The remainder of this section discusses the pre-processing required to create monthly ORL files for the remainder of the on_noadj sector (#3 above).

EPA/OTAQ created the NMIM 2005v2 onroad mobile CAP/HAP emissions for all states and sources using the MOBILE6 model version M6023ChcOxFixNMIM. The CO_2 emissions were removed, along with emissions of dioxins and furans and emissions that were replaced by MOVES and California-submitted data. The onroad refueling emissions were also removed since the NEI treats onroad refueling as a stationary source that is included in the nonpt sector (gasoline distribution, Stage II, SCC=2501060100), and can be found in the point sector in a handful of states (gasoline distribution Stage II; vapor loss or unclassified, SCC=40600401, 40600402, 40600403, and 40600499 in California, Colorado, Kentucky, and North Carolina).

Emissions were converted from monthly totals to monthly average-day based the on number of days in each month. Furthermore, this sector includes exhaust, evaporative, brake wear and tire wear emissions from onroad sources, which allowed us to use speciation profiles that are specific to each of these processes. The 2007 VMT database was based on 2002 VMT grown to 2007 based on Federal Highway Administration (FWHA) data, unless state-provided VMT was available.

3.2.9 Nonroad Mobile Sources—NMIM-Based Nonroad (nonroad)

The nonroad sector includes monthly exhaust, evaporative and refueling emissions from nonroad engines (not including commercial marine, aircraft, and locomotives) derived from NMIM for all states except California. The NMIM configuration relied on the version of the NONROAD2005 model (NR05c-BondBase) used for the marine spark ignited (SI) and small SI engine proposed rule, published May 18, 2007 (EPA, 2007c). For 2007, the NONROAD2005 model (NR05c-BondBase) is equivalent to NONROAD2008a, since it incorporated Bond rule revisions to some of the base case inputs and the Bond rule controls did not take effect until future years. As with the onroad emissions, NMIM provides nonroad emissions for VOC by three emission modes: exhaust, evaporative and refueling. Unlike the onroad sector, refueling emissions for nonroad sources are not dropped from processing for this sector.

EPA/OTAQ ran NMIM to create county-SCC emissions for the 2007 nonroad mobile CAP/HAP inventory. In a similar process as for the on_noadj sector, California NMIM emissions were removed and replaced with emissions submitted by California, but scaled to 2007 using linear interpolation of year 2005 and 2009 inventories. Emissions were converted from monthly totals to monthly average-day based the on number of days in each month. Similar to onroad NMIM emissions, EPA default inputs were replaced by state inputs where provided. The NMIM inventory documentation describes this and all other details of the NMIM nonroad emissions development for the 2005v4 platform:

ftp://ftp.epa.gov/EmisInventory/2005_nei/mobile/2005_mobile_nei_version_2_report.pdf

California monthly nonroad emissions are year 2007 and are based on linearly-interpolated September 2007 California Air Resources Board (CARB) submitted inventories for the years 2005 and 2009. NH_3 emissions are from NMIM runs for California because these were not included in the California NEI submittal. HAP emissions were estimated by applying HAP-to-CAP ratios computed from California data in the NEI 2005 v2 submittal. Only those HAPs that are also estimated by NMIM for nonroad mobile sources were retained; all other HAPs were dropped.

The CARB-based nonroad data did not have mode-specific data for VOC (exhaust, evaporative, and refueling). The annual total California data was split into monthly, mode-specific nonroad emissions for California using the NMIM results. Details on this process are documented separately (Strum, 2007). Nonroad refueling emissions for California were computed as Gasoline Transport (SCC=2505000120) emissions multiplied by a factor of 0.46 (to avoid double counting with portable fuel container (PFC) emissions in the nonpt sector) and were allocated to the gasoline equipment types based on ratios of evaporative-mode VOC. The factor of 0.46 was computed by dividing the NMIM-derived California refueling for 2005 by the sum of portable fuel container emissions and NMIM-derived refueling for 2005.

3.2.10 Nonroad Mobile Sources: Aircraft, Locomotive and Commercial Marine (alm_no_c3)

The alm_no_c3 sector contains CAP and HAP emissions from locomotive and commercial marine sources, except for category 3/residual-fuel (C3) commercial marine vessels. In previous modeling platforms, this sector also contained aircraft emissions, but here aircraft emissions have been removed from the sector because point-source airports were provided in the 2005 NEI v2 point source inventory and are included as part of the ptnonipm sector. Note that the C3 commercial marine vessel emissions are in the seca_c3 sector. Note that the "a" in the "alm_no_c3" sector name is now misleading because aircraft are no longer in this sector.

The remaining emissions in the alm_no_c3 sector are year 2002 emissions unchanged from the 2002 platform. The 2005v4 platform documentation has a complete list of SCCs found in the alm_no_c3 sector. The documentation of the 2002 NEI for the alm sector is available at: http://www.epa.gov/ttn/chief/net/2002inventory.html#documentation.

For modeling purposes, the following additional changes were made to the data in this sector for the 2005v4 platform:

- Removed C3 CMV SCCs (residual fuel) and aircraft SCCs.
- Removed railway maintenance emissions (SCCs 2285002015, 2285004015, and 2285006015) because these are included in the nonroad NMIM monthly inventories. This change was made for the 2002 platform and is retained here in the 2005 platform.
- For the purpose of CAP-HAP VOC integration, removed benzene, formaldehyde, and acetaldehyde for all sources for which these HAPs were not integrated with VOC. These sources are considered no-integrate when the source of data between VOC and VOC HAPs is inconsistent or VOC analysis of VOC and VOC HAPs indicates the source is not integrated. Although the CAP-HAP integration approach also required the removal of methanol for no-integrate sources, the only sources in this sector that included methanol were in California, where the integrate approach was used for all sources and therefore did not need to remove it.

The 2002 platform documentation goes into greater detail on the locomotives and C1/C2 CMV emissions.

3.2.11 Nonroad mobile sources: C3 commercial marine (seca_c3)

The raw seca_c3 sector emissions data were developed in an ASCII raster format used since the Emissions Control Area-International Marine Organization (ECA-IMO) project began in 2005, then known as the Sulfur Emissions Control Area (SECA). These emissions consist of large marine diesel engines (at or above 30 liters/cylinder) that until very recently, were allowed to meet relatively modest emission requirements, often burning residual fuel. The emissions in this sector are comprised of primarily foreign-flagged ocean-going vessels, referred to as Category 3 (C3) ships. The seca_c3 (ECA) inventory includes these ships in ports and underway mode and includes near-port auxiliary engines. An overview of the ECA-IMO project and future year goals for reduction of NO_X, SO_2, and PM C_3 emissions can be found at:

http://www.epa.gov/oms/regs/nonroad/marine/ci/420f09015.htm

The base year ECA inventory is 2002 and consists of these CAPs: PM_{10}, CO, CO_2, NH_3, NO_X, SO_X (assumed to be SO_2), and Hydrocarbons (assumed to be VOC). EPA developed regional growth (activity-based) factors that were applied to create a 2007 inventory from the 2002 data. These growth factors are provided in Table 3-5 and are mapped and documented in the following report:

http://www.epa.gov/oms/regs/nonroad/marine/ci/420r09007-chap2.pdf

These growth factors are the same for all pollutants except NO_X which includes a Tier 1 Standard.

Region	NOx	All_other pollutants
Alaska	1.114	1.179
East Coast	1.182	1.251
Gulf Coast	1.092	1.156
Hawaii	1.212	1.282
North Pacific (Washington)	1.114	1.179
South Pacific (Oregon and California)	1.212	1.282
Great Lakes	1.082	1.089

Table 3-5. Regional growth factors used to project 2002 C3 emissions to 2007

The raw ECA inventory started as a set of ASCII raster (pixel image) dataset emissions at approximately 4-km resolution that was converted to SMOKE point-source ORL input format as described in this conference paper:

http://www.epa.gov/ttn/chief/conference/ei17/session6/mason.pdf

This paper describes how the ASCII raster dataset was converted to latitude-longitude, mapped to state/county FIPS codes that extend up to 200 nautical miles (nm) from the coast, assigned stack parameters, and how the monthly ASCII raster dataset emissions were used to create monthly temporal profiles. Counties were assigned as extending up to 200nm from the coast because of this was the distance through the Exclusive Economic Zone (EEZ), a distance that would be used to define the outer limits of the Emissions Control Area-International Marine Organization (ECA-IMO) controls for these vessels.

The 2007 ECA-based C_3 inventory does not delineate between ports and underway (or other C_3 modes such as hoteling, maneuvering, reduced-speed zone, and idling) emissions. Therefore, these emissions were assigned to the broad ("total") SCC for C_3 CMV (2280003000). This has no effect on temporal allocation or speciation compared to existing profiles for underway and port C_3 emissions (2280003100 and 2280003200).

Factors were applied to compute HAP emissions (based on emissions ratios) to VOC to obtain HAP emissions values. Table 3-6 shows these factors. Because HAPs were computed

directly from the CAP inventory and the calculations are therefore consistent, the entire seca_c3 sector utilizes CAP-HAP VOC integration to use the VOC HAP species directly, rather than VOC speciation profiles.

Pollutant	Apply to	Pollutant Code	Factor
Acetaldehyde	VOC	75070	0.0002286
Benzene	VOC	71432	9.795E-06
Formaldehyde	VOC	50000	0.0015672

Table 3-6. HAP emission ratios for generation of HAP emissions from criteria emissions for C3 commercial marine vessels

The emissions were converted to SMOKE point source ORL format, allowing for the emissions to be allocated to modeling layers above the surface layer. All non-US emissions (i.e., in waters considered outside of the 200nm EEZ, and hence out of the U.S. territory) are assigned a dummy state/county FIPS code=98001. The SMOKE-ready data have also been cropped from the original ECA-IMO data to cover only the 36-km CMAQ domain, which is the largest domain used for this effort, and larger than the 12km domain used in this project.

3.2.12 Emissions from Canada, Mexico and Offshore Drilling Platforms (othpt, othar, othon)

The emissions from Canada, Mexico, and Offshore Drilling Platforms are included as part of three sectors: othpt, othar, and othon. The "oth" refers to the fact that these emissions are "other" than those in the 2005 NEI, and the third and fourth characters provide the SMOKE source types: "pt" for point, "ar" for "area and nonroad mobile", and "on" for onroad mobile. Mexico's emissions are unchanged from the 2002 Platform with one exception –one stack diameter was updated (recomputed from stack velocity and flowrate) in the Mexico border states point inventory.

For Canada, year 2006 emissions were used, with several modifications:

i. Wildfires and prescribed burning emissions were not included because Canada does not include these inventory data in their modeling.

ii. In-flight aircraft emissions were not included because these are also not included for the U.S. modeling.

iii. A 75% reduction ("transport fraction") to PM for the road dust, agricultural, and construction emissions in the Canadian "afdust" inventory. This approach is more simplistic than the county-specific approach used for the U.S., but a comparable approach was not available for Canada.

iv. Speciated VOC emissions from the ADOM chemical mechanism were not included.

v. Residual fuel CMV (C3) SCCs (22800030X0) were removed because these emissions are included in the seca_c3 sector, which covers not only emissions close to Canada but also emissions far at sea. Canada was involved in the inventory development of the seca_c3 sector emissions.

vi. Wind erosion (SCC=2730100000) and cigarette smoke (SCC=2810060000) emissions were removed from the nonpoint (nonpt) inventory; these emissions are also absent from the U.S. inventory.

vii. Quebec $PM_{2.5}$ emissions (2,000 tons/yr) were removed for one SCC (2305070000) for Industrial Processes, Mineral Processes, Gypsum, Plaster Products due to corrupt fields after conversion to SMOKE input format. This error should be corrected in a future inventory.

viii. Excessively high CO emissions were removed from Babine Forest Products Ltd (British Columbia plantid='5188') in the point inventory. This change was made because the value of the emissions was impossibly large.

ix. The county part of the state/count FIPS code field in the SMOKE inputs were modified in the point inventory from "000" to "001" to enable matching to existing temporal profiles.

For Mexico emissions for 1999 (Eastern Research Group Inc., 2006) were used as these were developed as part of a partnership between Mexico's Secretariat of the Environment and Natural Resources (Secretaría de Medio Ambiente y Recursos Naturales-SEMARNAT) and National Institute of Ecology (Instituto Nacional de Ecología-INE), the U.S. EPA, the Western Governors' Association (WGA), and the North American Commission for Environmental Cooperation (CEC). This inventory includes emissions from all states in Mexico.

The offshore emissions include point source offshore oil and gas drilling platforms. Updated offshore emissions from the 2005 NEI v2 point source inventory were used. The offshore sources were provided by the Mineral Management Services (MMS).

3.2.13 SMOKE-ready non-anthropogenic chlorine inventory

For the ocean chlorine, the same data as in the CAP and HAP 2002-based Platform was used. See ftp://ftp.epa.gov/EmisInventory/2002v3CAPHAP/documentation for details.

3.3 Emissions Modeling Summary

The CMAQ model requires hourly emissions of specific gas and particle species for the horizontal and vertical grid cells contained within the modeled region (i.e., modeling domain). To provide emissions in the form and format required by CMAQ, it is necessary to "pre-process" the "raw" emissions (i.e., emissions input to SMOKE) for the sectors described above. In brief, this processing step transforms these emissions from their original temporal resolution, pollutant resolution, and spatial resolution into the data required by CMAQ. The temporal resolution of the emissions input to

SMOKE for the 2005 Platform varies across sectors, and may be hourly, monthly, or annual total emissions. The spatial resolution, which also can be different for different sectors, may be individual point sources or county totals (province totals for Canada, municipio totals for Mexico).

The pollutants for all sectors except for biogenics and ocean chlorine are those inventoried for the NEI. The pre-processing steps involving temporal allocation, spatial allocation, pollutant speciation, and vertical allocation of point sources are referred to as emissions modeling. This section provides some basic information about the tools and data files other than inventories used for emissions modeling as part of the 2005 Platform.

3.3.1 The SMOKE Modeling System

SMOKE version 2.6 was used to pre-process the raw emissions to create the emissions inputs for CMAQ. SMOKE executables and source code are available from the Community Multiscale Analysis System (CMAS) Center at http://www.cmascenter.org.

3.3.2 Key Emissions Modeling Settings

Emissions inventories for each sector are processed separately through SMOKE to create gridded, hourly, speciated emissions. The final merge program (Mrggrid) is then run to combine the model-ready, sector-specific emissions across sectors. The SMOKE settings in the "run scripts" and the data in the SMOKE ancillary files control the approaches used by the individual SMOKE programs for each sector. Table 3-7 summarizes the major processing steps of each platform sector. The "Spatial" column shows the spatial approach: "point" indicates that SMOKE maps the source from a point (i.e., latitude and longitude) location to a grid cell, "surrogates" indicates that some or all of the sources use spatial surrogates to allocate county emissions to grid cells, and "area-to-point" indicates that some of the sources use the SMOKE area-to-point feature to grid the emissions. The "Speciation" column indicates that all sectors use the SMOKE speciation step, though speciation of biogenic emissions is done within BEIS3 and not as a separate SMOKE step. The "Inventory resolution" column shows the inventory temporal resolution from which SMOKE needs to calculate hourly emissions.

Finally, the "plume rise" column indicates the sectors for which the in-line approach is used. These sectors are the only ones which will have emissions in aloft layers, based on plume rise. For the 2005 Platform, SMOKE was not used to compute vertical plume rise; this was done in CMAQ using stack data in SMOKE output files for each model-ready sector. The one sector with "in-line" only, seca_c3, was processed so that the entire emissions would be in aloft layers. Thus, there were no seca_c3 emissions in the 2-dimensional, layer-1 files created by SMOKE. Rather the speciated and temporalized source-based CMAQ inputs for seca_c3 were used for the vertical allocation.

Platform sector	Spatial	Speciation	Inventory resolution	Plume rise
ptipm	point	Yes	daily & hourly	in-line
ptnonipm	point	Yes	annual	in-line
othpt	point	Yes	annual	in-line
nonroad	surrogates & area-to-point	Yes	monthly	
othar	surrogates	Yes	annual	
seca_c3	point	Yes	annual	in-line
alm_no_c3	surrogates & area-to-point	Yes	annual	
on_noadj	surrogates	Yes	monthly	
on_moves_startpm	surrogates	Yes	monthly	
on_moves_runpm	surrogates	Yes	monthly	
othon	surrogates	Yes	annual	
nonpt	surrogates & area-to-point	Yes	annual	
ag	surrogates	Yes	annual	
afdust	surrogates	Yes	annual	
beis	pre-gridded landuse	in BEIS	hourly	
ptfire	point	Yes	daily	in-line

Table 3-7. Key emissions modeling steps by sector

One of the issues found was that when using in-line processing, the PELVCONFIG file cannot allow grouping, otherwise the "inline" versus "offline" (i.e., processing whereby SMOKE creates 3-dimensional files) will not give identical results. Since a PELVCONFIG file with grouping was used, the in-line approach should be used to exactly replicate our results.

3.3.3 Spatial Configuration

For this project, we ran SMOKE and CMAQ were run for a 12-km modeling domain as shown in Figure 3-3. The grid used a Lambert-Conformal projection, with Alpha = 33, Beta = 45 and Gamma = -97, with a center of X = -97 and Y = 40. Later sections provide details on the spatial surrogates and area-to-point data used to accomplish spatial allocation with SMOKE.

3.3.4 Chemical Speciation Configuration

The emissions modeling step for chemical speciation creates "model species" needed by the air quality model for a specific chemical mechanism. These model species are either individual chemical compounds or groups of species, called "model species." The chemical mechanism used for the 2005 Platform is the Carbon Bond 05 (CB05) mechanism (Yarwood, 2005) with secondary organic aerosol (SOA) and

Figure 3-3. CMAQ Modeling Domain

HONO enhancements as described in

http://www.cmascenter.org/help/model_docs/cmaq/4.7/RELEASE_NOTES.txt.

From the perspective of emissions preparation, it is the same mechanism used in the 2002 Platform except that additional input model species are needed to support the nitrous acid (HONO) chemistry enhancements and additional input model species are needed to support SOA. Table 3-8 lists the model species produced by SMOKE for use in CMAQ. The only three input species that were not in the CAP 2002-Based Platform described in 2002 "CAP-only" Platform (http://www.epa.gov/scram001/reports/Emissions%20TSD%20Vol1_02-28-08.pdf) are nitrous acid (HONO), BENZENE and sesquiterpenes (SESQ). It should be noted that the BENZENE model species is not part of CB05 in that the concentrations of BENZENE do not provide any feedback into the chemical reactions (i.e., it is not "inside" the chemical mechanism). Rather, benzene is used as a reactive tracer and as such is impacted by the CB05 chemistry. BENZENE, along with several reactive CBO5 species (such as TOL and XYL) plays a role in SOA formation in CMAQ4.7.

The approach for speciating $PM_{2.5}$ emissions is the same as that described for the 2002 platform except that two of the onroad sectors, and Canadian emissions contained pre-speciated PM emissions which were not further speciated in SMOKE . The approach for speciating VOC emissions from non-biogenic sources is different in two major ways: 1) for some sources, HAP emissions are used in the speciation process to allow integration of VOC and HAP emissions in the NEI. This has the result of modifying the speciation profiles based on the HAP emission estimates which are presumed to be more accurate than the speciated VOC results for the HAPs; and, 2) for some mobile sources, "combination" profiles are specified by county and month and emission mode (e.g., exhaust, evaporative). SMOKE computes the resultant profile on the fly given the fraction of each specific profile to use for the county, month and emission mode. A new feature and new profile file in SMOKE (the GSPRO_COMBO file) allowed the use of this approach for the 2005 Platform.

Inventory Pollutant	Model Species	Model species description
CO	CO	Carbon monoxide
NO_X	NO	Nitrogen oxide
	NO2	Nitrogen dioxide
	HONO	Nitrous acid
SO_2	SO2	Sulfur dioxide
	SULF	Sulfuric acid vapor
NH_3	NH3	Ammonia
VOC	ALD2	Acetaldehyde
	ALDX	Propionaldehyde and higher aldehydes
	BENZENE	Benzene (not part of CB05)
	ETH	Ethene
	ETHA	Ethane
	ETOH	Ethanol
	FORM	Formaldehyde
	IOLE	Internal olefin carbon bond (R-C=C-R)
	ISOP	Isoprene
	MEOH	Methanol
	OLE	Terminal olefin carbon bond (R-C=C)
	PAR	Paraffin carbon bond
	TOL	Toluene and other monoalkyl aromatics
	XYL	Xylene and other polyalkyl aromatics
Various additional VOC species from the biogenics model which do not map to the above model species	SESQ	Sesquiterpenes
	TERP	Terpenes
PM_{10}	PMC	Coarse PM > 2.5 microns and ≤ 10 microns
$PM_{2.5}$	PEC	Particulate elemental carbon ≤ 2.5 microns
	PNO3	Particulate nitrate ≤ 2.5 microns
	POC	Particulate organic carbon (carbon only) ≤ 2.5 microns
	PSO4	Particulate Sulfate ≤ 2.5 microns
	PMFINE	Other particulate matter ≤ 2.5 microns

Table 3-8. Model Species produced by SMOKE for CB05 with SOA for CMAQ 4.7

The VOC speciation approach for the 2005 Platform differed from the 2002 Platform in that, for some of the U.S. platform sectors, HAP emissions from the NEI were included in the speciation process. That is, instead of speciating VOC to generate all of the species listed in Table 3-8 as was done for the 2002 platform, emissions of the 4 HAPs, benzene, acetaldehyde, formaldehyde and methanol (BAFM) from the NEI were integrated with the NEI VOC. The integration process (described in more detail below) combines the BAFM HAPs with the VOC in a way that does not double count emissions and uses the BAFM directly in the speciation process. Generally, the HAP emissions from the NEI are believed to be more representative of emissions of these compounds than their generation via VOC speciation.

The BAFM HAPs were chosen because, with the exception of BENZENE, they are the only explicit VOC HAPs in the base version of CMAQ 4.7 (CAPs only with chlorine chemistry) model. By "explicit VOC HAPs," we mean model species that participate in the modeled chemistry using the CB05 chemical mechanism. The use of these HAP emission estimates along with VOC is called "HAP-CAP integration". BENZENE was chosen because it was added as a model species in the base version of CMAQ 4.7, and there was a desire to keep its emissions consistent between multi-pollutant and base versions of CMAQ.

The integration of HAP VOC with VOC is a feature available in SMOKE for all inventory formats other than PTDAY (the format used for the ptfire sector). SMOKE allows the user to specify the particular HAPs to integrate and the particular sources to integrate. The particular HAPs to integrate are specified in the INVTABLE file, and the particular sources to integrate are based on the NHAPEXCLUDE file (which actually provides the sources that are *excluded* from integration[11]). For the "integrate" sources, SMOKE subtracts the "integrate" HAPs from the VOC (at the source level) to compute emissions for the new pollutant "NONHAPVOC." The user provides NONHAPVOC-to-NONHAPTOG factors and NONHAPTOG speciation profiles. SMOKE computes NONHAPTOG and then applies the speciation profiles to allocate the NONHAPTOG to the other CMAQ VOC species not including the integrated HAPs. This process is illustrated in Figure 3-4. Note that BAFM emissions do not need to be removed from no-integrate sources in a sector where all sources are no-integrate because this is accomplished by through use of a SMOKE ancillary "INVTABLE" which essentially drops all the BAFM in that sector. CAP-HAP integration was considered for all sectors and developed "integration criteria" for some of those. Table 3-9 summarizes the integration approach for each platform sector used in Step 1 of Figure 3-4.

[11] In SMOKE version 2.6 the options to specify sources for integration are expanded so that a user can specify the particular sources to include or exclude from integration, and there are settings to include or exclude all sources within a sector.

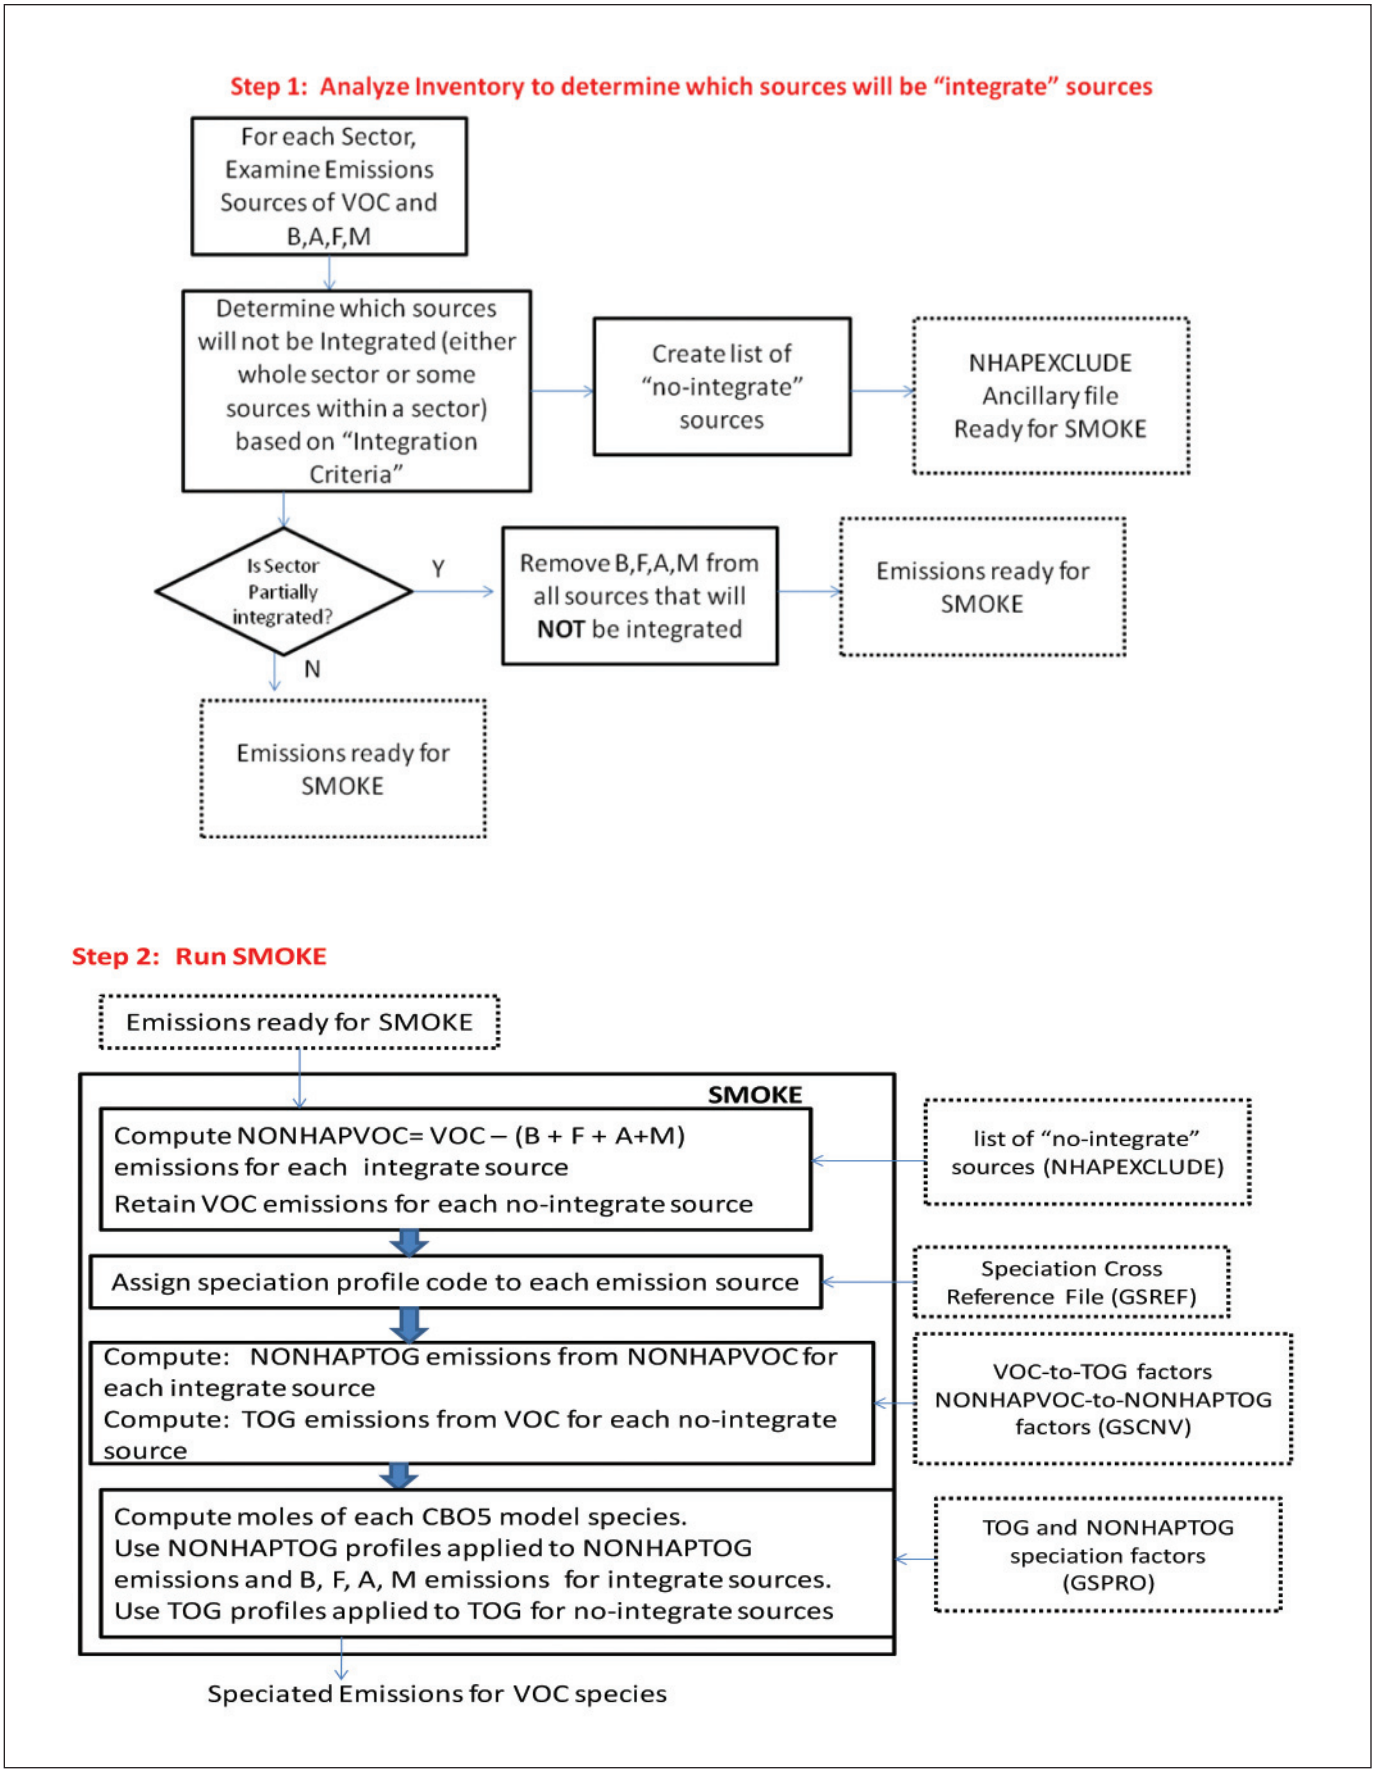

Figure 3-4. Process of integrating BAFM with VOC for use in VOC Speciation

PLATFORM SECTOR	Approach for Integrating NEI emissions of Benzene (B), Acetaldehyde (A), Formaldehyde (F) and Methanol (M)
ptipm	No integration because emissions of BAFM are relatively small for this sector
ptnonipm	No integration because emissions of BAFM are relatively small for this sector and it is not expected that criteria for integration would be met by a significant number of sources
ptfire	Full integration (However, NONHAPVOC computed outside of SMOKE since SMOKE cannot do this calculation for the day-specific fire formatted files)
ag	N/A—sector contains no VOC
afdust	N/A—sector contains no VOC
nonpt	Partial integration; details provided below table
nonroad	For other than California: Partial integration—did not integrate CNG or LPG sources (SCC beginning with 2268 or 2267) because NMIM computed only VOC and not any HAPs for these SCCs. For California: Full integration
alm_no_c3	Partial integration; details provided below table
seca_c3	Full integration
onroad	Full integration
biog	N/A—sector contains no inventory pollutant "VOC"; but rather specific VOC species
othpt	No integration—not the NEI
othar	No integration—not the NEI
othon	No integration—not the NEI

Table 3-9. Integration status of benzene, acetaldehyde, formaldehyde and methanol (BAFM) for each platform sector

For the nonpt sector, the following integration criteria were used to determine the sources to integrate (Step 1):

1. Any source for which B, A, F or M emissions were from the 1996 NEI were not integrated (data source code contains a "96"),
2. Any source for which the sum of B, A, F, or M is greater than the VOC was not integrated, since this clearly identifies sources for which there is an inconsistency between VOC and VOC HAPs. This includes some cases in which VOC for a source is zero.
3. For certain source categories (those that comprised 80% of the VOC emissions), sources were selected for integration in the category per the criteria specified in the first column in Table 3-5. For most of these source categories, sources are allowed to be integrated if they had the minimum combination of B,A,F and M specified in the first column. For a few source categories, all sources were designated as "no-integrate".
4. For source categories not covered in Table 3-5 (i.e., that do not comprise the top 80%of VOC emissions), then as long as the source has emissions of one of the B, F, A or M pollutants, then it can be integrated.

For the alm_no_c3 sector, the integration criteria were (1) that the source had to have at least one of the 4 HAPs and (2) that the sum of BAFM could not exceed the VOC emissions. The criteria for this sector were less complex than the nonpt sector because it has much fewer source categories.

The SMOKE feature to compute speciation profiles from mixtures of other profiles in user-specified proportions was used in this project. The combinations are specified in the GSPRO_COMBO ancillary file by pollutant (including pollutant mode, e.g., EXH__VOC), state and county (i.e., state/county FIPS code) and time period (i.e., month). This feature was used for onroad and nonroad mobile and gasoline-related related stationary sources. These emission sources use fuels with varying ethanol content, and therefore the speciation profiles require different combinations of gasoline, E10 an E85 profiles. Since the ethanol content varies spatially (e.g., by state or county), temporally (e.g., by month) and by modeling year (future years have more ethanol) the combo feature allows combinations to be specified at various levels for different years.

3.3.5 Temporal Processing Configuration

Table 3-10 summarizes the temporal aspect of the emissions processing configuration. It compares the key approaches used for temporal processing across the sectors. The temporal aspect of SMOKE processing is controlled through (a) the scripts T_TYPE (Temporal type) and M_TYPE (Merge type) settings and (b) ancillary data files. In addition to the resolution, temporal processing includes a ramp-up period for several days prior to January 1, 2007, intended to mitigate the effects of initial condition concentrations. The ramp up period for the national 12km grid was 10 days. For most sectors, the emissions from late December of 2007 were used to provide emissions for the end of December, 2006.

3.3.6 Vertical Allocation of Emissions

Table 3-7 specifies the sectors for which plume rise is calculated. If there is no plume rise for a sector, the emissions are placed into layer 1 of the air quality model. Vertical plume rise was performed in-line within CMAQ for this

Platform sector	Inventory resolution	Monthly profiles used?	Daily temporal approach 1,2	Merge processing approach 1,3	Process Holidays as separate days?
ptipm	daily & hourly		all	all	yes
ptnonipm	annual	yes	mwdss	all	yes
othpt	annual	yes	mwdss	all	
nonroad	monthly		mwdss	mwdss	yes
othar	annual	yes	mwdss	mwdss	
alm_no_c3	annual	yes	mwdss	mwdss	
seca_c3	annual	yes	mwdss	mwdss	
on_noadj	monthly		week	week	yes
on_moves_startpm	monthly		week	week	yes
on_moves_runpm	monthly		week	week	yes
othon	annual	yes	week	week	
nonpt	annual	yes	mwdss	mwdss	yes
ag	annual	yes	aveday	aveday	
afdust	annual	yes	aveday	aveday	
beis	hourly		n/a	n/a	
ptfire	daily		all	all	

[1] **Definitions for processing resolution:**

all = hourly emissions computed for every day of the year, inventory is already daily

week = hourly emissions computed for all days in one "representative" week, representing all weeks for each month, which means emissions have day-of-week variation, but not week-to-week variation within the month

mwdss= hourly emissions for one representative Monday, representative weekday, representative Saturday and representative Sunday for each month, which means emissions have variation between Mondays, other weekdays, Saturdays and Sundays within the month, but not week-to-week variation within the month. Also Tuesdays, Wednesdays and Thursdays are treated the same.

aveday = hourly emissions computed for one representative day of each month, which means emissions for all days of each month are the same.

[2] **Daily temporal approach** refers to the temporal approach for getting daily emissions from the inventory using the Temporal program. The values given are the values of the L_TYPE setting.

[3] **Merge processing approach** refers to the days used to represent other days in the month for the merge step. If not "all", then the SMOKE merge step just run for representative days, which could include holidays as indicated by the rightmost column. The values given are the values of the M_TYPE setting.

Table 3-10. Temporal Settings Used for the Platform Sectors in SMOKE

study for all of the SMOKE point-source sectors (ptipm, ptnonipm, othpt, and seca_c3). The in-line plume rise computed within CMAQ is nearly identical to the plume rise that would be calculated within SMOKE using the Laypoint program. See http://www.smoke-model.org/version2.6/html/ch06s07.html for full documentation of Laypoint. The selection of point sources for plume rise is pre-determined in SMOKE using the Elevpoint program (http://www.smoke-model.org/version2.6/html/ch06s03.html). The calculation is done in conjunction with the CMAQ model time steps with interpolated meteorological data and is therefore more temporally resolved than it is when done in SMOKE. Also, the calculation of the location of the point source is slightly different than the one used in SMOKE and this can result in slightly different placement of point sources near grid cell boundaries.

For point sources, the stack parameters are used as inputs to the Briggs algorithm, but point fires do not have stack parameters. However, the ptfire inventory does contain data on the acres burned (acres per day) and fuel consumption (tons fuel per acre) for each day. CMAQ uses these additional parameters to estimate the plume rise of emissions into layers above the surface model layer. Specifically, these data are used to calculate heat flux, which is then used to estimate plume rise. In addition to the acres burned and fuel consumption, heat content of the fuel is needed to compute heat flux. The heat content was assumed to be 8000 Btu/lb of fuel for all fires because specific data on the fuels were unavailable in the inventory.

The plume rise algorithm applied to the fires is a modification of the Briggs algorithm with a stack height of zero and a heat release estimated from the fuel loading and fire size. CMAQ uses the Briggs algorithm to determine the plume top and bottom, and then computes the plumes' distributions into the vertical layers that the plumes intersect. The pressure difference across each layer divided by the pressure

Code	Surrogate Description	Code	Surrogate Description

Table 3-11. U.S. Surrogates Available for the 2002 and 2005 Platforms

difference across the entire plume is used as a weighting factor to assign the emissions to layers. This approach gives plume fractions by layer and source.

3.3.7 Emissions Modeling Ancillary Files

In this section the ancillary data that SMOKE used to perform spatial allocation, chemical speciation, and temporal allocation for the 2005 Platform is summarized. The ancillary data files, particularly the cross-reference files, provide the specific inventory resolution at which spatial, speciation, and temporal factors are applied. For the 2005 Platform, spatial factors were generally applied by country/SCC, speciation factors by pollutant/SCC or (for combination profiles) state/county FIPS code and month, and temporal factors by some combination of country, state, county, SCC, and pollutant.

3.3.7.1 Spatial Allocation Ancillary Files

Spatial allocation was performed for a national 12-km domain. To do this, SMOKE used national 12-km spatial surrogates and a SMOKE area-to-point data file. For the U.S. and Mexico, the same spatial surrogates were used as were used for the 2002 Platform. For Canada, a new set of Canadian surrogates provided by Environment Canada was used as they were provided along with their 2006 emissions data.

3.3.7.2 Surrogates for U.S. Emissions

There are 66 spatial surrogates available for spatially allocating U.S. county-level emissions to the CMAQ 36-km and 12-km grid cells; they are the same as for the 2002 Platform. An area-to-point approach overrides the use of surrogates for some sources. The Surrogate Tool was used to generate all of the surrogates. The shapefiles input to the Surrogate Tool are provided and documented at http://www.epa.gov/ttn/chief/emch/spatial/spatialsurrogate.html. The document ftp://ftp.epa.gov/EmisInventory/emiss_shp2006/us/list_of_shapefiles.pdf provides a list and summary of these shapefiles. The detailed steps in developing the county boundaries for the surrogates are documented at ftp://ftp.epa.gov/EmisInventory/emiss_shp2006/us/metadata_for_2002_county_boundary_shapefiles_rev.pdf. Table 3-11 lists the codes and descriptions of the surrogates.

The onroad off-network (parking area) emissions from the MOVES model, new to the 2005 platform, were spatially allocated as shown in Table 3-12.

SCC & Description	Surrogate
2201001350 Light Duty Gas Vehicles- parking areas rural 2201002350 Light Duty Gas Trucks 1&2- parking areas rural 2201004350 Light Duty Gas Trucks 3&4- parking areas rural	Rural population (same as rural local roads), code= 130
2201001370 Light Duty Gas Vehicles- parking areas urban 2201002370 Light Duty Gas Trucks 1&2- parking areas urban 2201004370 Light Duty Gas Trucks 3&4- parking areas urban	Urban population (same as urban local roads), code =120

Table 3-12. Surrogate assignments to new mobile categories in the 2005 Platform

3.3.7.3 Allocation Method for Airport-Related Sources in the U.S.

There are numerous airport-related emission sources in the 2005 NEI, such as aircraft, airport ground support equipment, and jet refueling. Unlike the 2002 platform in which most of these emissions were contained in sectors with county-level resolution—alm (aircraft), nonroad (airport ground support) and nonpt (jet refueling), the 2005 platform includes the aircraft emissions as point sources. Aircraft emissions are part of the ptnonipm sector, since the 2005v2 inventory included them as point sources.

Thus, for the 2005 platform, the SMOKE "area-to-point" approach was used for only airport ground support equipment (nonroad sector), and jet refueling (nonpt sector). The approach is described in detail in the 2002 Platform documentation: http://www.epa.gov/scram001/reports/Emissions%20TSD%20Vol1_02-28-08.pdf.

Nearly the same ARTOPNT file was used to implement the area-to-point approach as was done for the CAP and HAP-2002-Based Platform. This was slightly updated from the CAP-only 2002 Platform by further allocating the Detroit-area airports into multiple sets of geographic coordinates to support finer scale modeling that was done under a different project. The updated file was retained for the 2005 Platform.

3.3.7.4 Surrogates for Canada and Mexico Emission Inventories

The Mexican emissions and single surrogate (population) were the same as were used in the 2002 Platform. For Canada, an updated set of surrogates was used to spatially allocate the 2006 Canadian emissions for the 2005 Platform. The updated set completely replaced the 2002 Platform surrogates for allocating the 2006 province-level Canadian emissions.

The updated surrogate data provided in the 2005v4 zip files and described in Table 3-13 came from Environment Canada. They provided both the surrogates and cross references; the surrogates were outputs from the Surrogate Tool (previously

referenced). Per Environment Canada, the surrogates are based on 2001 Canadian census data. The cross-references that Canada originally provided were updated as follows: all assignments to surrogate '978' (manufacturing industries) were changed to '906' (manufacturing services), and all assignments to '985' (construction and mining) and '984' (construction industries) were changed to '907' (construction services) because the surrogate fractions in 984, 978 and 985 did not sum to 1. Codes for surrogates other than population that did not begin with the digit "9" were also changed.

3.3.7.5 Chemical Speciation Ancillary Files

The following data file, provided at the 2005v4 website, contains the SMOKE inputs used for chemical speciation of the inventory species to the CMAQ model species. SMOKE environmental variable names, used in the file names, are shown using capital letters in parentheses:

- **ancillary_2005v4_smokeformat.zip:** inventory table

1: Not used because fractions did not sum to 1;

2: Surrogates 986, 987, 988 and 989 were originally numbered by Canada as 611, 615, 620 and 65, respectively. We changed the numbers so that all Canadian surrogates would begin with "9".

Table 3-13. Canadian Spatial Surrogates for 2005-based platform Canadian Emission

(INVTABLE), NONHAPVOC emissions calculation exclusions file (NHAPEXCLUDE), speciation cross references (GSREF), speciation VOC-to-TOG conversion factors (GSCNV) , speciation profiles (GSPRO), and combined, monthly speciation profiles (GSPRO_COMBO).

For VOC speciation, SMOKE-ready profiles for the CB05 chemical mechanism were generated using the Speciation Tool (Eyth, 2006):

- TOG-to-model species (used only for no-integrate sources)
- NONHAPTOG-to-model species (used only for the integrate sources)
- TOG-to-BENZENE (used only for no-integrate sources)

Speciation profile entries were added that map NEI emissions of benzene, acetaldehyde, formaldehyde and methanol to the model species BENZENE, ALD2, FORM and METHANOL, respectively. These profiles were used only for the integrate sources. Note that the integrate and no-integrate sources were processed using the same GSREF and GSPRO files. Thus, to avoid double counting of these HAP species, B, A, F and M emissions were removed for all no-integrate sources in the inventory. If the entire sector was no-integrate, then these could be removed in SMOKE (by using "N" in the INVTABLE); but if a sector was partially integrated, these HAPS had to be removed from the actual inventory input to SMOKE, but only for the no HAP use, no-integrate sources.

In addition to the speciation profiles, the Speciation Tool generates the SMOKE-ready speciation conversion files (GSCNV). Two of these were generated: one containing profile-specific VOC-to-TOG conversion factors and the other containing profile-specific NONHAPVOC-to-NONHAPTOG conversion factors.

The TOG and $PM_{2.5}$ speciation factors that are the basis of the chemical speciation approach were developed from the SPECIATE 4.2 database (http://www.epa.gov/ttn/chief/software/speciate/index.html) which is EPA's repository of TOG and PM speciation profiles of air pollution sources. The 2002-based platform utilized an earlier version, SPECIATE 4.0. Note that this update did not impact the $PM_{2.5}$ profiles we used with the 2005-based platform; they were the same as those used for the 2002-based platform.

As with SPECIATE 4.0, SPECIATE 4.2 development was a collaboration involving EPA's ORD and EPA's Office of Air Quality Planning and Standards (OAQPS) at Research Triangle Park, NC, and Environment Canada (EPA, 2006c). The SPECIATE database contains speciation profiles for TOG, speciated into individual chemical compounds, VOC-to-TOG conversion factors associated with the TOG profiles, and speciation profiles for $PM_{2.5}$. The database also contains the $PM_{2.5}$ speciated into both individual chemical compounds (e.g., zinc, potassium, manganese, lead), and into the "simplified" $PM_{2.5}$ components used in the air quality model. These simplified components are:

- PSO4 : primary particulate sulfate
- PNO3: primary particulate nitrate
- PEC: primary particulate elemental carbon
- POC: primary particulate organic carbon
- PMFINE: other primary particulate, less that 2.5 microns in diameter

One minor issue found with the $PM_{2.5}$ speciation which was similarly an issue with the 2002-based platform is that a bituminous coal combustion profile (92095) that is applicable to numerous inventory sources was used, but only for a single nonpoint SCC (2101002000). For the other SCCs pertaining to bituminous coal combustion we used the sub-bituminous coal combustion profile (92084). Table 3-14 shows the differences are shown below, though these are quite small and represent only a minor change to the SMOKE results:

Another issue was that profile 92095 was inadvertently left out of SPECIATE4.2 (and 4.0). It was obtained from EPA ORD staff using it in their modeling applications.

Key changes to the TOG profiles from the 2002 Platform are as follows:

- Updated the profile for aircraft from 1098 (Aircraft Landing/Takeoff (LTO)—Commercial) which is from SPECIATE3.2 and has a profile date of 1989, to 5565 (Aircraft Exhaust), which has a profile date of 8/2008 and is based on testing conducted in 2005).
- Updated the profile for forest fires from 0307 (Miscellaneous Burning - Forest Fires) which was from SPECIATE3.2 and has a profile date of 1989) to 5560 (Biomass Burning - Extratropical Forest, dated 2/2008 and was based on testing conducted in 2001)
- Changed the assignment of residential wood combustion (including woodstove and fireplace emissions) and other profiles that formerly used 4641 (Fireplace wood combustion-oak wood) to 4642 (Fireplace wood combustion-pine wood) because of all three woods tested in the study (oak, pine and eucalyptus), the most complete testing was done for the pine wood (for example, benzene was only measured for pine)
- Updated the profiles for mobile onroad and nonroad sources to use more up-to-date test data. The updated profiles are:
  - 8750: Gasoline Exhaust—Reformulated gasoline
  - 8751: Gasoline Exhaust—E10 ethanol gasoline
  - 8752[12]: Gasoline Exhaust—E85 ethanol gasoline
  - 8753: Gasoline Vehicle - Evaporative emission - Reformulated gasoline

[12] Profile not used in 2005, but used in future years built off of the 2005 base year.

pollutant	species	split factors sub-bituminous 92084	split factors bituminous 92095
PM2_5	PEC	0.0188	0.01696
PM2_5	PMFINE	0.8266	0.827928
PM2_5	PNO3	0.0016	0.00208
PM2_5	POC	0.0263	0.026307
PM2_5	PSO4	0.1267	0.126725

Table 3-14. Differences between two profiles used for coal combustion

  - 8754: Gasoline Vehicle - Evaporative emission - E10 ethanol gasoline
  - 8755[9]: Gasoline Vehicle - Evaporative emission - E85 ethanol gasoline
  - 8756[9,13]: Composite Profile for Tier 2 vehicles E0, exhaust
  - 8757[9,10]: Composite Profile for Tier 2 vehicles E10, exhaust
- Utilized combination profiles comprised of the above updated exhaust and evaporative profiles to match the average ethanol content of fuels used by different counties and for different months of the year. Combinations were created based on the fuel properties data in the NMIM county database.

Speciation profiles for use with BEIS are not included in SPECIATE. The 2005 Platform uses BEIS 3.14 and includes a new species (SESQ) that was not in BEIS 3.13 (the version used for the 2002 Platform). This species was therefore added (it is mapped to the CMAQ species SESQT) to the set of profiles that had been used in the 2002 Platform. The profile code associated with BEIS3.14 profiles for use with CB05 uses the same as in the 2002 Platform: "B10C5."

The INVTABLE and NHAPEXCLUDE SMOKE input files have a critical function in the VOC speciation process for emissions modeling cases utilizing HAP-CAP integration, as is done for the 2005 Platform.

Two different INVTABLE files were prepared to use with different sectors of the platform. For sectors in which we chose no integration across the entire sector, a "no HAP use" INVTABLE that set the "KEEP" flag to "N" for BAFM was created. Thus, any BAFM in the inventory input into SMOKE would be dropped. This approach both avoids double-counting of these species and assumes that the VOC speciation is the best available approach for these species for the sectors using the approach. The second INVTABLE, used for sectors in which one or more sources are integrated, causes SMOKE to keep the BAFM pollutants and indicates that they are to be integrated with VOC (by setting the "VOC or TOG component" field to "V" for all four HAP pollutants.

Sector-specific NHAPEXCLUDE files were developed that provide the specific sources that are excluded from integration.

3.3.7.6 Temporal Allocation Ancillary Files

The emissions modeling step for temporal allocation creates the 2005 hourly emission inputs for CMAQ by adjusting the emissions from the inventory resolution (annual, monthly, daily or hourly) that are input into SMOKE. The temporal resolution of each of the platform sectors prior to their input into SMOKE is included in the sector descriptions from Table 3-1 and were repeated in the discussion of temporal settings.

The starting point for the temporal profiles was the 2002 Platform. The monthly, weekly, and diurnal temporal profiles and associated cross references used to create the 2005 hourly emissions inputs for CMAQ were generally based on the temporal allocation data used for the 2002 Platform. New profile assignments were added for SCCs in the 2005 inventory that were not in the 2002 inventory, and the profiles used for ptipm sources without CEM data were updated to represent the year 2007. Temporal profiles were assigned for the new parking area SCCs provided by the draft version of MOVES and are shown in Figure 3-5. The remainder of this section discusses the development of the new temporal profiles or profile assignments used in the 2005 Platform.

The next development for the 2005 Platform included the addition of diurnal profiles for electric generating units (ptipm). The state-specific and pollutant-specific diurnal profiles for use in allocating the day-specific emissions for non-CEM sources in the ptipm sector were updated. The 2007 CEM data was used to create state-specific, day-to-hour factors, averaged over the whole year and all units in each state. Diurnal factors were calculated using CEM SO_2 and NO_X emissions and heat input. SO_2 and NO_X-specific factors were computed from the CEM data for these pollutants. All other pollutants used factors created from the hourly heat input data. The resulting profiles were assigned by state and pollutant.

[13] Profile not included in SPECIATE4.2 (Nov. 2008), per OTAQ documentation, profiles were created October 2008, by OTAQ with EPAct Phase 1 data, 22 out of 22 valid test cycles. Three vehicles tested: Honda Civic, Toyota Sienna, Chevy Silverado. Composite emission factors calculated using straight weighting for an LA92 drive cycle (1.19 miles, 8.63 miles, 1.19 miles for Bags 1,2 and 3, respectively).

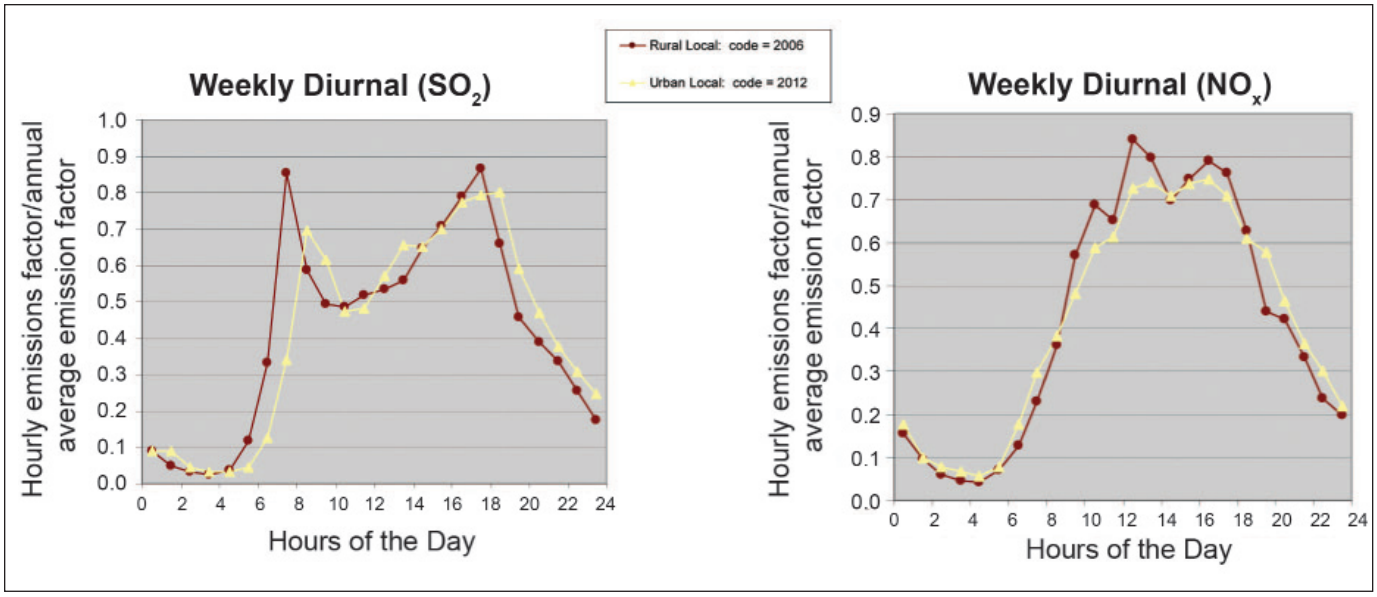

Figure 3-5. Diurnal Profiles for Parking Areas (Pollutants: SO_2 and NOx)

Canadian emission inventories were also included in the 2005 Platform. The temporal profile assignments for the Canadian 2006 inventory were provided by Environment Canada along with the inventory. They provided profile assignments that rely on the existing set of temporal profiles in the 2002 Platform. For point sources, they provided profile assignments by PLANTID.

Finally, WRAP oil and gas inventory profiles were included in the 2005 Platform. The WRAP 2005 oil and gas inventory SCCs[14] utilized uniform monthly and day of week profiles (codes 262 and 7, respectively) and an hourly profile (code 26) that put emissions in every hour, but weighted towards the day light hours.

[14] See Table 2-9: 2310000220, 2310000330, 2310000440, 2310010100, 2310010200, 2310010300, 2310010700, 2310010800, 2310020600, 2310020700, 2310020800, 2310021100, 2310021300, 2310021400, 2310021500, 2310021600, 2310023000, 2310030210, 2310030220

4.0
CMAQ Air Quality Model Estimates

4.1 Introduction to the CMAQ Modeling Platform

The Clean Air Act (CAA) provides a mandate to assess and manage air pollution levels to protect human health and the environment. EPA has established National Ambient Air Quality Standards (NAAQS), requiring the development of effective emissions control strategies for such pollutants as ozone and particulate matter. Air quality models are used to develop these emission control strategies to achieve the objectives of the CAA.

Historically, air quality models have addressed individual pollutant issues separately. However, many of the same precursor chemicals are involved in both ozone and aerosol (particulate matter) chemistry; therefore, the chemical transformation pathways are dependent. Thus, modeled abatement strategies of pollutant precursors, such as volatile organic compounds (VOC) and NOx to reduce ozone levels, may exacerbate other air pollutants such as particulate matter.

To meet the need to address the complex relationships between pollutants, EPA developed the Community Multiscale Air Quality (CMAQ) modeling system. The primary goals for CMAQ are to:

- Improve the environmental management community's ability to evaluate the impact of air quality management practices for multiple pollutants at multiple scales.
- Improve the scientist's ability to better probe, understand, and simulate chemical and physical interactions in the atmosphere.

The CMAQ modeling system brings together key physical and chemical functions associated with the dispersion and transformations of air pollution at various scales. It was designed to approach air quality as a whole by including state-of-the-science capabilities for modeling multiple air quality issues, including tropospheric ozone, fine particles, toxics, acid deposition, and visibility degradation. CMAQ relies on emission estimates from various sources, including the U.S. EPA Office of Air Quality Planning and Standards' current emission inventories, observed emission from major utility stacks, and model estimates of natural emissions from biogenic and agricultural sources. CMAQ also relies on meteorological predictions that include assimilation of meteorological observations as constraints. Emissions and meteorology data are fed into CMAQ and run through various algorithms that simulate the physical and chemical processes in the atmosphere to provide estimated concentrations of the pollutants. Traditionally, the model has been used to predict air quality across a regional or national domain and then to simulate the effects of various changes in emission levels for policymaking purposes. For health studies, the model can also be used to provide supplemental information about air quality in areas where no monitors exist.

CMAQ was also designed to have multi-scale capabilities so that separate models were not needed for urban and regional scale air quality modeling. The grid spatial resolutions in past annual CMAQ runs have been 36 km x 36 km per grid for the "parent" domain, and nested within that domain are 12 km x 12 km grid resolution domains. The parent domain typically covered the continental United States, and the nested 12 km x 12 km domain covered the Eastern or Western United States. The CMAQ simulation performed for this 2007 assessment used a single domain that covers the entire continental U.S. (CONUS) and large portions of Canada and Mexico using 12 km by 12 km horizontal grid spacing. For urban applications, CMAQ has also been applied with a 4-km x 4-km grid resolution for urban core areas; however, the uncertainties in emissions and meteorology information can actually increase at this high of a resolution. Currently, 12 km x 12 km resolution is recommended for most applications as the highest resolution. With the temporal flexibility of the model, simulations can be performed to evaluate longer term (annual to multi-year) pollutant climatologies as well as short-term (weeks to months) transport from localized sources. By making CMAQ a modeling system that addresses multiple pollutants and different temporal and spatial scales, CMAQ has a "one atmosphere" perspective that combines the efforts of the scientific community. Improvements will be made to the CMAQ modeling system as the scientific community further develops the state-of-the-science.

For more information on CMAQ, go to http://www.epa.gov/asmdnerl/CMAQ or http://www.cmascenter.org.

4.1.1 Advantages and Limitations of the CMAQ Air Quality Model

An advantage of using the CMAQ model output for comparing with health outcomes is that it has the potential to provide complete spatial and temporal coverage. Additionally, meteorological predictions, which are also needed when comparing health outcomes, are available for every grid cell along with the air quality predictions.

A disadvantage of using CMAQ is that, as a deterministic model, it has none of the statistical qualities of interpolation techniques that fit the observed data to one degree or another. Furthermore, the emissions and meteorological data used in CMAQ each have large uncertainties, in particular for unusual emission or meteorological events. There are also uncertainties associated with the chemical transformation and fate process algorithms used in air quality models.

Thus, emissions and meteorological data plus modeling uncertainties cause CMAQ to predict best on longer time scale bases (e.g., synoptic, monthly, and annual scales) and be most error prone at high time and space resolutions compared to direct measures.

One practical disadvantage of using CMAQ model output for health outcome research is that the regularly spaced grid cells do not line up directly with counties or ZIP codes which are the geographical units over which health outcomes are likely to be aggregated. But it is possible to overlay grid cells with county or ZIP code boundaries and devise means of assigning an exposure level that nonetheless provides more complete coverage than that available from ambient data alone. Another practical disadvantage is that CMAQ requires significant data and computing resources to obtain results for daily environmental health surveillance.

This section describes the air quality modeling platform used for the 2007 CMAQ simulation. A modeling platform is a structured system of connected modeling-related tools and data that provide a consistent and transparent basis for assessing the air quality response to changes in emissions and/or meteorology. A platform typically consists of a specific air quality model, emissions estimates, a set of meteorological inputs, and estimates of "boundary conditions" representing pollutant transport from source areas outside the region modeled. We used the CMAQ[15] model as part of the 2007 Platform to provide a national scale air quality modeling analysis. The CMAQ model simulates the multiple physical and chemical processes involved in the formation, transport, and destruction of ozone and fine particulate matter ($PM_{2.5}$).

This section provides a description of each of the main components of the 2007 CMAQ simulation along with the results of a model performance evaluation in which the 2007 model predictions are compared to corresponding measured concentrations.

4.2 CMAQ Model Version, Inputs and Configuration

4.2.1 Model Version

CMAQ is a non-proprietary computer model that simulates the formation and fate of photochemical oxidants, including $PM_{2.5}$ and ozone, for given input sets of meteorological conditions and emissions. The CMAQ model version 4.7 was most recently peer-reviewed in February of 2009 for the U.S. EPA.[16] As mentioned previously, CMAQ includes numerous science modules that simulate the emission, production, decay, deposition and transport of organic and inorganic gas-phase and particle-phase pollutants in the atmosphere. This analysis employed a version of CMAQ based on the latest publicly released version of CMAQ (i.e., version 4.7.1[17]) at the time of the 2007 air quality modeling. CMAQ version 4.7.1 reflects updates to version 4.7 to improve the underlying science which include aqueous chemistry mass conservation improvements and improved vertical convective mixing. The model enhancements in version 4.7.1 also include:

1. Aqueous chemistry
   - Mass conservation improvements
     + Imposed 1 second minimum timestep for remainder of the cloud lifetime

       after 100 "iterations" in the solver
     + Force mass balance for the last timestep in the cloud by limiting oxidized amount to mass available
   - Implemented steady state assumption for OH
   - Only allow sulfur oxidation to control the aqueous chemistry solver timestep (previously, reactions of OH, GLY, MGLY, and Hg for multipollutant model also controlled the timestep)
2. Advection
   - Added additional divergence-based constraint on advection timestep
   - Vertical advection in the Yamo module is now represented with the PPM scheme to limit numerical diffusion
3. Model time step determination
   - Fixed a potential advection time step error
     + The sum of the advection steps for a given layer time step might not equal the output time step duration in some extreme cases
     + Ensured that the advection steps sum up to the synchronization step
4. Horizontal diffusion
   - Fixed a potential error
     + Concentration data may not be correctly initialized if multiple sub-cycle time steps are required
     + Fix to initialize concentrations with values calculated in the previous sub-time step
5. Emissions
   - Bug fix in EMIS_DEFN.F to include point source layer 1 NH3 emissions
   - Bug fix to calculate soil NO "pulse" emissions in BEIS

[16] Allen, D., Burns, D., Chock, D., Kumar, N., Lamb, B., Moran, M. (February 2009 Draft Version). Report on the Peer Review of the Atmospheric Modeling and Analysis Division, NERL/ORD/EPA. U.S. EPA, Research Triangle Park, NC. CMAQ version 4.7 was released on December, 2008. It is available from the Community Modeling and Analysis System (CMAS) as well as previous peer-review reports at: http://www.cmascenter.org.

[17] CMAQ version 4.7.1 model code is available from the Community Modeling and Analysis System (CMAS) at: http://www.cmascenter.org.

- Remove excessive logging of cases where ambient air temperature exceeds 315.0 Kelvin. When this occurs, the values are just slightly over 315
- Bug fix for parallel decomposition errors in plume rise emissions

6. Photolysis
   - JPROC/phot_table and phot_sat options
     + Expanded lookup tables to facilitate applications across the globe and vertical extent to 20km
     + Updated temperature adjustments for absorption cross sections and quantum yields
     + Revised algorithm that processes TOMS datasets for OMI data format
   - In-line option
     + Asymmetry factor calculation updated using values from Mie theory integrated over log normal particle distribution; added special treatment for large particles in asymmetry factor algorithm to avoid numerical instabilities

	National 12 km CMAQ Modeling Configuration
Map Projection	Lambert Conformal Projection
Grid Resolution	12 km
Coordinate Center	97 W, 40 N
True Latitudes	33 and 45 N
Dimensions	459 x 299 x 24
Vertical extent	24 Layers: Surface to 50 mb level (see Table 4-2)

Table 4-1. Geographic Information for 12 km Modeling Domain

4.2.2 Model Domain and Grid Resolution

The CMAQ modeling analyses were performed for a domain covering the continental United States, as shown in Figure 4-1. This single domain covers the entire continental U.S. (CONUS) and large portions of Canada and Mexico using 12 km by 12 km horizontal grid spacing. The model extends vertically from the surface to 50 millibars (approximately 19 km) using a sigma-pressure coordinate system. Air quality conditions at the outer boundary of the 12 km domain were taken from a global model. Table 4-1 provides some basic geographic information regarding the 12 km CMAQ domain.

Figure 4-1. Map of the CMAQ Modeling Domain. The blue box denotes the 12 km national modeling domain (Same as Figure 3-3.)

4.2.3 Modeling Period / Ozone Episodes

The 12 km CMAQ modeling domain was modeled for the entire year of 2007. The 2007 annual simulation was performed in two half-year segments (i.e., January through June, and July through December) for each emissions scenario. With this approach to segmenting an annual simulation we were able to reduce the overall throughput time for an annual simulation. The annual simulation included a "ramp-up" period, comprised of 10 days before the beginning of each half-year segment, to mitigate the effects of initial concentrations. All 365 model days were used in the annual average levels of $PM_{2.5}$. For the 8-hour ozone, we used modeling results from the period between May 1 and September 30. This 153-day period generally conforms to the ozone season across most parts of the U.S. and contains the majority of days that observed high ozone concentrations.

4.2.4 Model Inputs: Emissions, Meteorology and Boundary Conditions

2007 Emissions: The emissions inventories used in the 2007 air quality modeling are described in Section 3, above.

Meteorological Input Data: The gridded meteorological data for the entire year of 2007 at the 12 km continental United States scale domain was derived from version 3.1 of the Weather Research and Forecasting Model (WRF), Advanced Research WRF (ARW) core.[18] Previous CMAQ annual simulations have typically utilized meteorology provided by the 5th Generation Mesoscale Model (MM5).[19] The WRF Model is a next-generation mesoscale numerical weather prediction system developed for both operational forecasting and atmospheric research applications (http://wrf-model.org). The 2007 WRF simulation included the physics options of the Pleim-Xiu land surface model (LSM), Asymmetric Convective Model version 2 planetary boundary layer (PBL) scheme, Morrison double moment microphysics, Kain-Fritsch cumulus parameterization scheme and the RRTMG long-wave radiation (LWR) scheme.[20]

The WRF meteorological outputs were processed to create model-ready inputs for CMAQ using the Meteorology-Chemistry Interface Processor (MCIP) package[21], version 3.6, to derive the specific inputs to CMAQ: horizontal wind components (i.e., speed and direction), temperature, moisture, vertical diffusion rates, and rainfall rates for each grid cell in each vertical layer. The WRF simulation used the same CMAQ map projection, a Lambert Conformal projection centered at (-97, 40) with true latitudes at 33 and 45 degrees north. The 12 km WRF domain consisted of 459 by 299 grid cells. The WRF simulation utilized 34 vertical layers with a surface layer of approximately 38 meters. Table 4-2 shows the vertical layer structure used in WRF and the layer collapsing approach to generate the CMAQ meteorological inputs. CMAQ resolved the vertical atmosphere with 24 layers, preserving greater resolution in the PBL.

In terms of the 2007 WRF meteorological model performance evaluation, an approach which included a combination of qualitative and quantitative analyses was used to assess the adequacy of the WRF simulated fields.[22] The qualitative aspects involved comparisons of the model-estimated synoptic patterns against observed patterns from historical weather chart archives. Additionally, the evaluations compared spatial patterns of monthly average rainfall and monthly maximum planetary boundary layer (PBL) heights. The statistical portion of the evaluation examined the model bias and error for temperature, water vapor mixing ratio, solar radiation, and wind fields. These statistical values were calculated on a monthly basis.

Initial and Boundary Conditions: The lateral boundary and initial species concentrations are provided by a three-dimensional global atmospheric chemistry model, the GEOS-CHEM[23] model version 8-02-03. The global GEOS-CHEM model simulates atmospheric chemical and physical processes driven by assimilated meteorological observations from the NASA's Goddard Earth Observing System (GEOS). This model was run for 2007 with a grid resolution of 2.0 degrees x 2.5 degrees (latitude-longitude) and 47 vertical layers. The predictions were used to provide one-way dynamic boundary conditions at three-hour intervals and an initial concentration field for the CMAQ simulations. A GEOS-Chem evaluation was conducted for the purpose of validating the 2007 GEOS-Chem simulation for selected measurements relevant to their use as boundary conditions for CMAQ and reproducing GEOS-Chem evaluation plots reported in the literature for previous versions of the model.[24] More information is available about the GEOS-CHEM model and other applications using this tool at: http://www-as.harvard.edu/chemistry/trop/geos.

4.3 CMAQ Model Performance Evaluation

An operational model performance evaluation for ozone and $PM_{2.5}$ and its related speciated components was conducted for the 2007 simulation using state/local monitoring sites data in order to estimate the ability of the CMAQ modeling system to replicate the 2007 base year concentrations for the 12 km continental U.S. domain.

There are various statistical metrics available and used by the science community for model performance evaluation. For a robust evaluation, the principal evaluation statistics used to evaluate CMAQ performance were two bias metrics, normalized mean bias and fractional bias; and two

Table 4-2. Vertical layer structure for 2007 WRF and CMAQ simulations (heights are layer top).

error metrics, normalized mean error and fractional error. Normalized mean bias (NMB) is used as a normalization to facilitate a range of concentration magnitudes. This statistic averages the difference (model - observed) over the sum of observed values. NMB is a useful model performance indicator because it avoids overinflating the observed range of values, especially at low concentrations. Normalized mean bias is defined as:

$$NMB = \frac{\sum_{1}^{n}(P\text{-}O)}{\sum_{1}^{n}(O)} *100$$, where P = predicted concentrations and O = observed

Normalized mean error (NME) is also similar to NMB, where the performance statistic is used as a normalization of the mean error. NME calculates the absolute value of the difference (model - observed) over the sum of observed values. Normalized mean error is defined as:

$$NME = \frac{\sum_{1}^{n}|P\text{-}O|}{\sum_{1}^{n}(O)} *100$$, where P = predicted concentrations and O = observed

Fractional Bias (FB) is defined as:

$$FB = \frac{1}{n}\left(\frac{\sum_{1}^{n}(P\text{-}O)}{\sum_{1}^{n}\left(\frac{(P+O)}{2}\right)}\right) *100$$, where P = predicted concentrations and O = observed

FB is a useful model performance indicator because it has the advantage of equally weighting positive and negative bias estimates. The single largest disadvantage in this estimate of model performance is that the estimated concentration (i.e., prediction, P) is found in both the numerator and denominator.

Fractional error (FE) is similar to fractional bias except the absolute value of the difference is used so that the error is always positive. Fractional error is defined as:

$$FE = \frac{1}{n}\left(\frac{\sum_{1}^{n}|P\text{-}O|}{\sum_{1}^{n}\left(\frac{(P+O)}{2}\right)}\right) *100$$, where P = predicted concentrations and O = observed

In addition to the performance statistics, regional maps which show the normalized mean bias and error were prepared for the ozone season, May through September, at individual monitoring sites as well as on an annual basis for PM2.5 and its component species.

Evaluation for 8-hour Daily Maximum Ozone: The operational model performance evaluation for hourly and eight-hour daily maximum ozone was conducted using the statistics defined above. Ozone measurements from 1176 sites for 2007 in the continental U.S. were included in the evaluation and were taken from the 2007 State/local monitoring site data in the Air Quality System (AQS) Aerometric Information Retrieval System (AIRS). The performance statistics were calculated using predicted and observed data that were paired in time and space on an hourly and/or 8-hour basis. Statistics were generated for the following geographic groupings: domain wide and four large sub-regions[25]: Midwest, Northeast, Southeast, Central, and Western U.S.

[25] The subregions are defined by States where: Midwest is IL, IN, MI, OH, and WI; Northeast is CT, DE, MA, MD, ME, NH, NJ, NY, PA, RI, and VT; Southeast is AL, FL, GA, KY, MS, NC, SC, TN, VA, and WV; Central is AR, IA, KS, LA, MN, MO, NE, OK, and TX; West is AK, CA, OR, WA, AZ, NM, CO, UT, WY, SD, ND, MT, ID, and NV.

The 8-hour ozone model performance bias and error statistics for each subregion and each season are provided in Table 4-4. Seasons were defined as: winter (December-January-February), spring (March-April-May), summer (June, July, August), and fall (September-October-November). Spatial plots of the normalized mean bias and error for individual monitors are shown in Figures 4-2 through 4-3. The statistics shown in these two figures were calculated over the ozone season using data pairs on days with observed 8-hour ozone of ≥ 60 ppb.

In general, the model performance statistics indicate that the 8-hour daily maximum ozone concentrations predicted by the 2007 CMAQ simulation closely reflect the corresponding 8-hour observed ozone concentrations in space and time in each subregion of the 12 km modeling domain. As indicated by the statistics in Table 4-4, bias and error for 8-hour daily maximum ozone are relatively low in each subregion, not only in the summer when concentrations are highest, but also during other times of the year. Specifically, 8-hour ozone in the summer is slightly over predicted with the greatest over prediction in the Central States (NMB is 19.6 percent). In the spring, ozone is slightly under predicted in all the subregions except in the Central states where NMB is near negligible (NMB is 0.2 percent). In the winter, when concentrations are generally low, the model under predicts 8-hour ozone with the exception of the West (NMB is 3.0). In the fall, when concentrations are also relatively low, ozone is slightly over predicted; with NMBs less than 12 percent in each subregion.

Subregion		No. of Obs	NMB (%)	NME (%)	FB (%)	FE (%)
Central States	Winter	11,223	-8.68	20.2	-10.3	24.7

Table 4-4. Summary of CMAQ 2007 8-Hour Daily Maximum O3 Model Performance Statistics by Subregion, by Season.

Model bias at individual sites during the ozone season is similar to that seen on a subregional basis for the summer. The information in Figure 4-2 indicates that the bias for days with observed 8-hour daily maximum ozone greater than 60 ppb is within ± 20 percent at the vast majority of monitoring sites across the U.S. domain. The exceptions are sites in and/or near Minneapolis, Duluth, District of Columbia, New York City, New Orleans, and San Antonio, as well as a few areas along the California coast. At these sites observed concentrations greater than 60 ppb are generally predicted in the range of ±20 to 40 percent. Looking at the map of bias, Figure 4-2 indicates that the low bias at these sites is not evident at other sites in these same areas. This suggests that the under prediction at these sites is likely due to very local features (e.g., meteorology and/or emissions) and not indicative of a systematic problem in the modeling platform. Model error, as seen from Figure 4-3, is 14 percent or less at most of the sites across the U.S. modeling domain. Somewhat greater error is evident at sites in several areas most notably along portions of the Northeast Corridor and in portions of Michigan, Minnesota, Louisiana, Texas, and the western most part of the modeling domain, (e.g., New Mexico, California, and Washington).

$PM_{2.5}$: The $PM_{2.5}$ evaluation focuses on $PM_{2.5}$ total mass and its components, including sulfate (SO_4), nitrate (NO_3), total nitrate ($TNO_3 = NO_3 + HNO_3$), ammonium (NH_4), elemental carbon (EC), and organic carbon (OC). The $PM_{2.5}$ bias and error performance statistics were calculated on an annual basis for each subregion (Table 4-5). $PM_{2.5}$ ambient measurements for 2007 were obtained from the following networks for model evaluation: Chemical Speciation Network (CSN—total of 211 sites, 24 hour average), Interagency Monitoring of PROtected Visual Environments (IMPROVE—total of 163 sites, 24 hour average), and Clean Air Status and Trends Network (CASTNet—total of 86, weekly average). For $PM_{2.5}$ species that are measured by more than one network, we calculated separate sets of statistics for each network by subregion. For brevity, Table 4-5 provides annual model performance statistics for $PM_{2.5}$ and its component species for the 12 km continental U.S. domain and the five sub-regions defined above (Northeast,

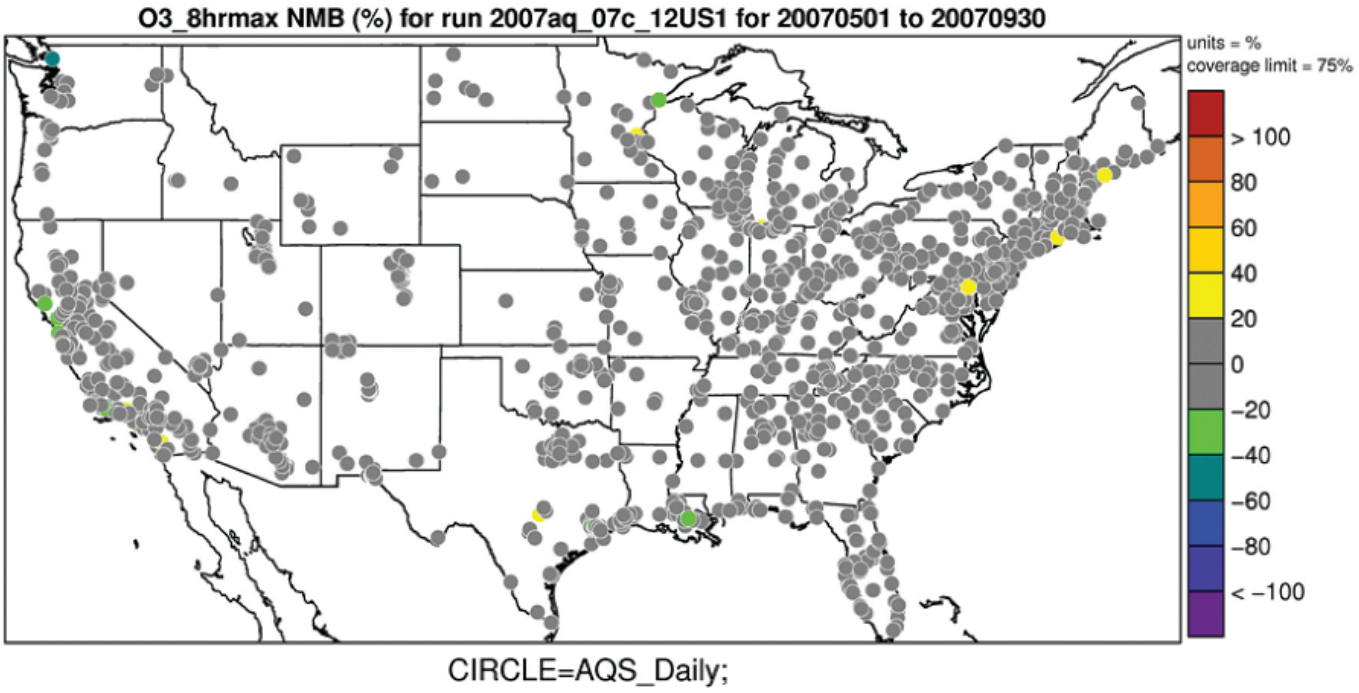

Figure 4-2. Normalized Mean Bias (%) of 8-hour daily maximum ozone greater than 60 ppb over the period May-September 2007 at monitoring sites in the continental U.S. modeling domain.

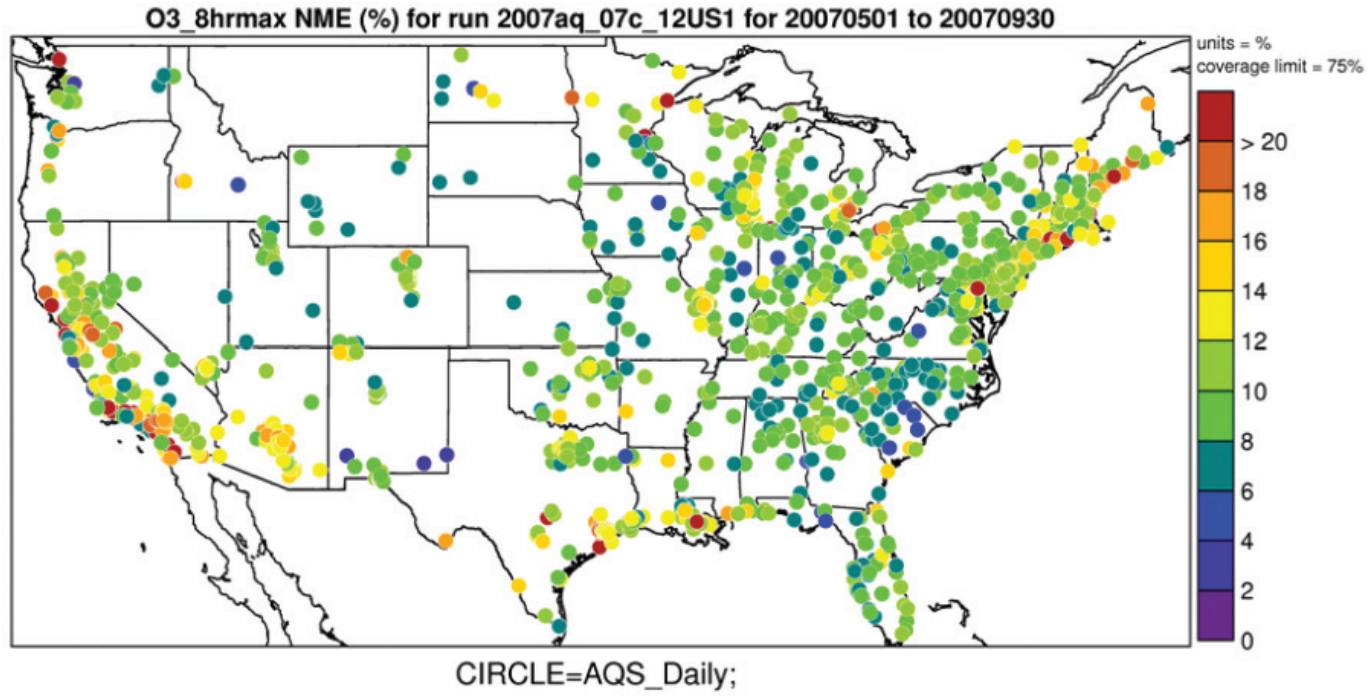

Figure 4-3. Normalized Mean Error (%) of 8-hour daily maximum ozone greater than 60 ppb over the period May-September 2007 at monitoring sites in the continental U.S. modeling domain.

Midwest, Southeast, Central, and West). In addition to the tabular summaries of bias and error statistics, annual spatial maps which show the normalized mean bias and error by site for each $PM_{2.5}$ species are provided in Figures 4-4 through 4-17.

As indicated by the statistics in Table 4-5, annual CMAQ $PM_{2.5}$ for 2007 shows a slight under prediction at rural IMPROVE monitoring sites in each subregion except the Northeast which shows an over prediction in NMB of 18.1 percent. Annual $PM_{2.5}$ at urban CSN monitoring sites show slight over predictions in the Midwest, Central and West whereas annual $PM_{2.5}$ is under predicted in the Southeast (NMB is -2.1 percent) and Northeast (NMB is -42.3).

Although not shown here, the mean observed concentrations of $PM_{2.5}$ are more than twice as high at the CSN sites (~16µg m^{-3}) as the IMPROVE sites (~ 6µg m^{-3}), thus illustrating the statistical differences between the urban CSN and rural IMPROVE networks.

Annual average sulfate is consistently under-predicted at CSN, IMPROVE, and CASTNet monitoring sites across the modeling domain, with NMB values ranging from -8 percent to -34 percent. Overall, sulfate bias performance is slightly better at urban CSN sites than at rural IMPROVE and/or suburban CASTNet sites. Sulfate performance shows moderate error, ranging from 22 to 45 percent. Annual model bias and error at individual sites, as displayed in Figures 4-6

Table 4-5. Summary of CMAQ 2007 Annual $PM_{2.5}$ Species Model Performance Statistic

and 4-7, suggest spatial patterns vary by region. The model bias for most of the Southeast, Central and Southwest states are within -20 to -40 percent. The model bias appears to be much less (±20 percent) in the Northeast, Midwest, and Northwest states. A few sites in the Northwest have biases much greater than 20 percent. Model error also shows a spatial trend by region, where much of the Eastern states are 20 to 30 percent, the Central U.S. states are 30 to 40 percent, and the Western states are greater than 40 percent.

Annual average nitrate is over predicted at the urban and rural monitoring sites in most of the subregions in the12 km modeling domain (NMB in the range of 24% to 93%), while nitrate is under predicted in the West (NMB in the range of -23% to -32%). The bias statistics indicate that the model performance for nitrate is generally best at the urban CSN monitoring sites. Model performance of total nitrate at suburban CASTNet monitoring sites shows an

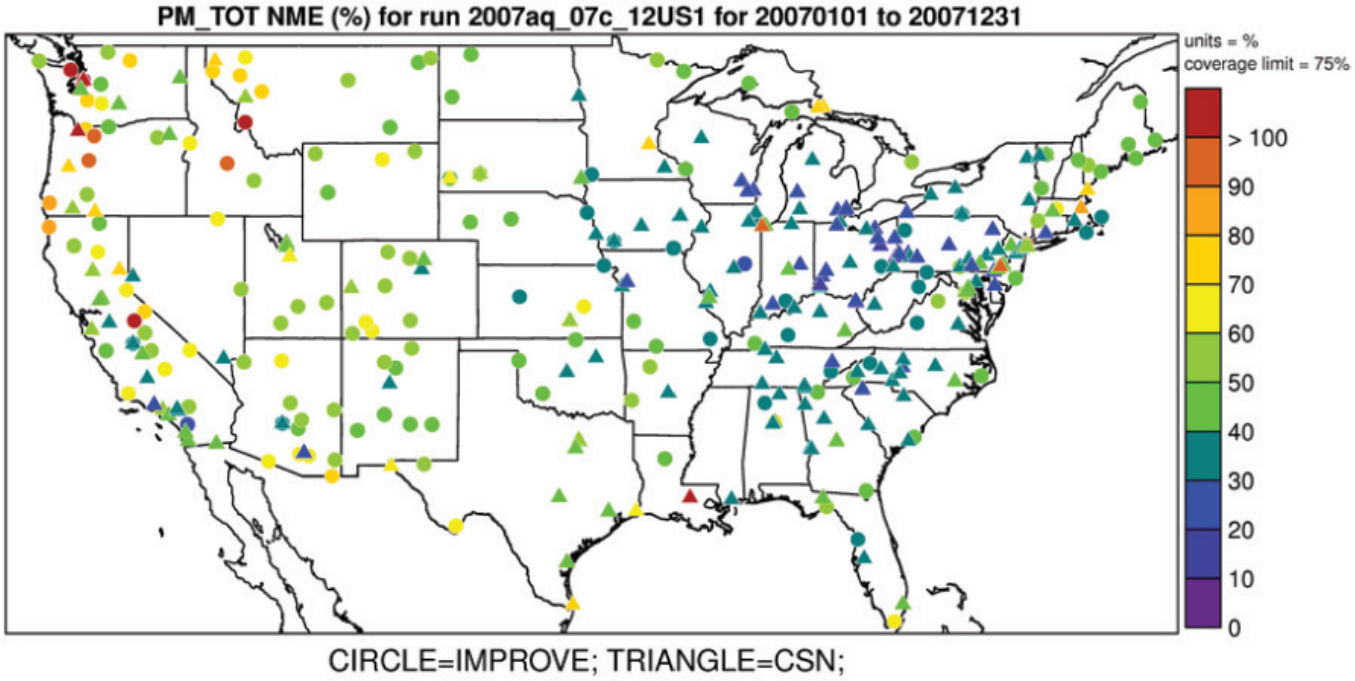

Figure 4-4. Normalized Mean Bias (%) of annual PM2.5 mass at monitoring sites in the continental U.S. modeling domain.

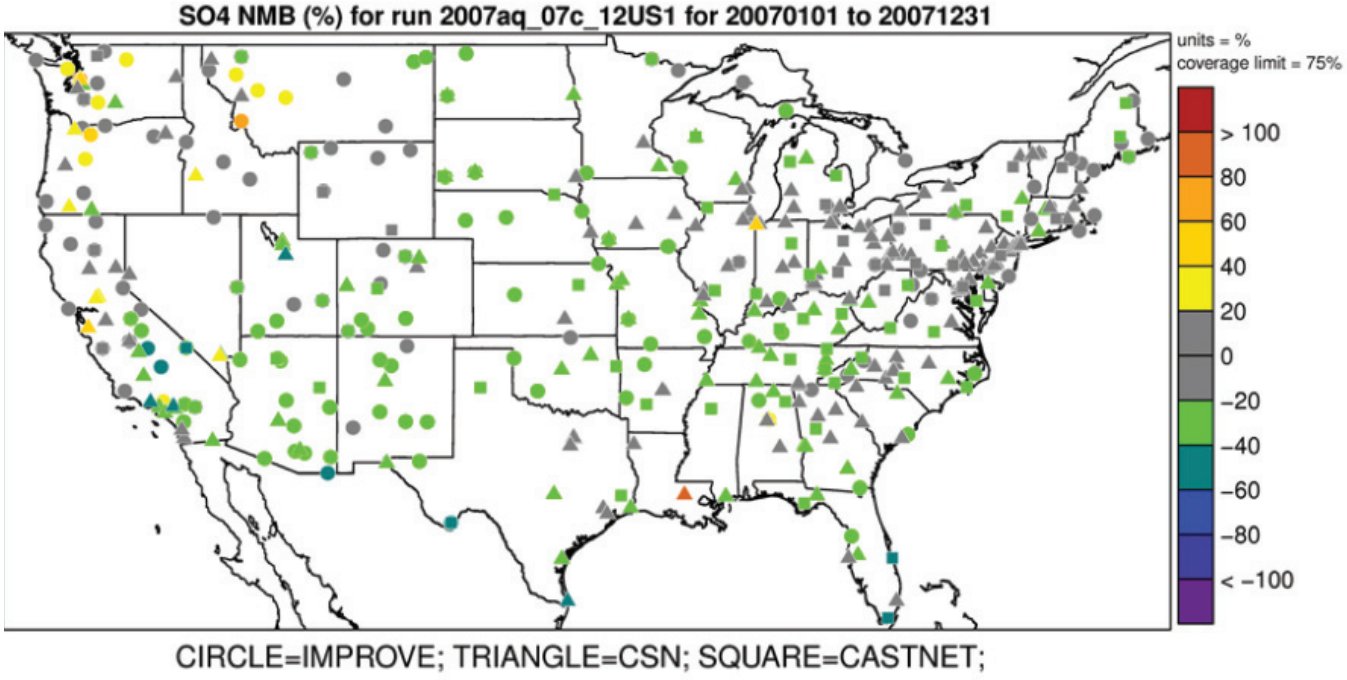

Figure 4-5. Normalized Mean Error (%) of annual PM2.5 mass at monitoring sites in the continental U.S. modeling domain.

over prediction across all subregions. Model error for nitrate is somewhat greater for each subregion as compared to sulfate. Model bias at individual sites indicates mainly over prediction of greater than 20 percent at most monitoring sites in the Eastern half of the U.S. as well and in the extreme Northwest, as indicated in Figure 4-8. The exception to this is in the Southwest of the modeling domain where there appears to be a greater number of sites with under prediction of nitrate of 20 to 80 percent. Model error for annual nitrate, as shown in Figure 4-9, is least at sites in portions of the Midwest and extending eastward to the Northeast corridor. Nitrate concentrations are typically higher in these areas than in other portions of the modeling domain.

Annual average ammonium model performance as indicated in Table 4-5 has a tendency for the model to slightly over predict in the Northeast, Midwest, and Central U.S. states across the CSN and CASTNet monitoring sites (NMB

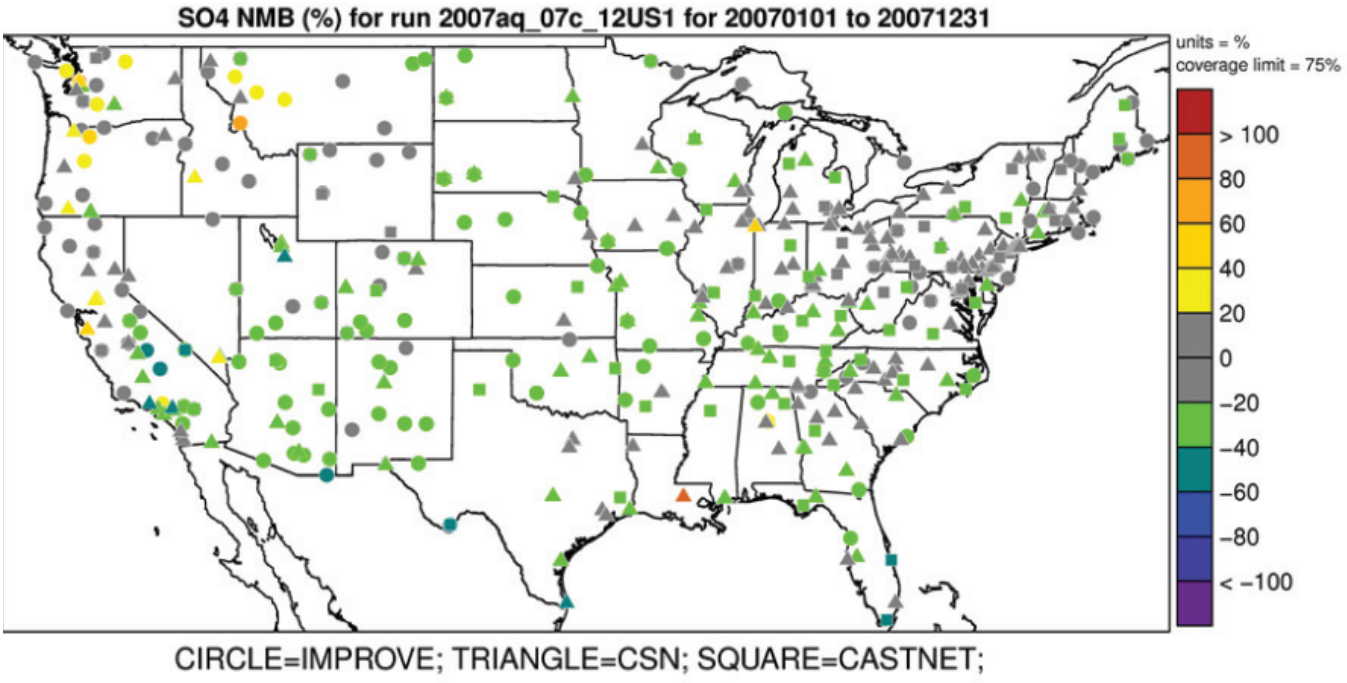

Figure 4-6. Normalized Mean Bias (%) of annual Sulfate at monitoring sites in the continental U.S. modeling domain.

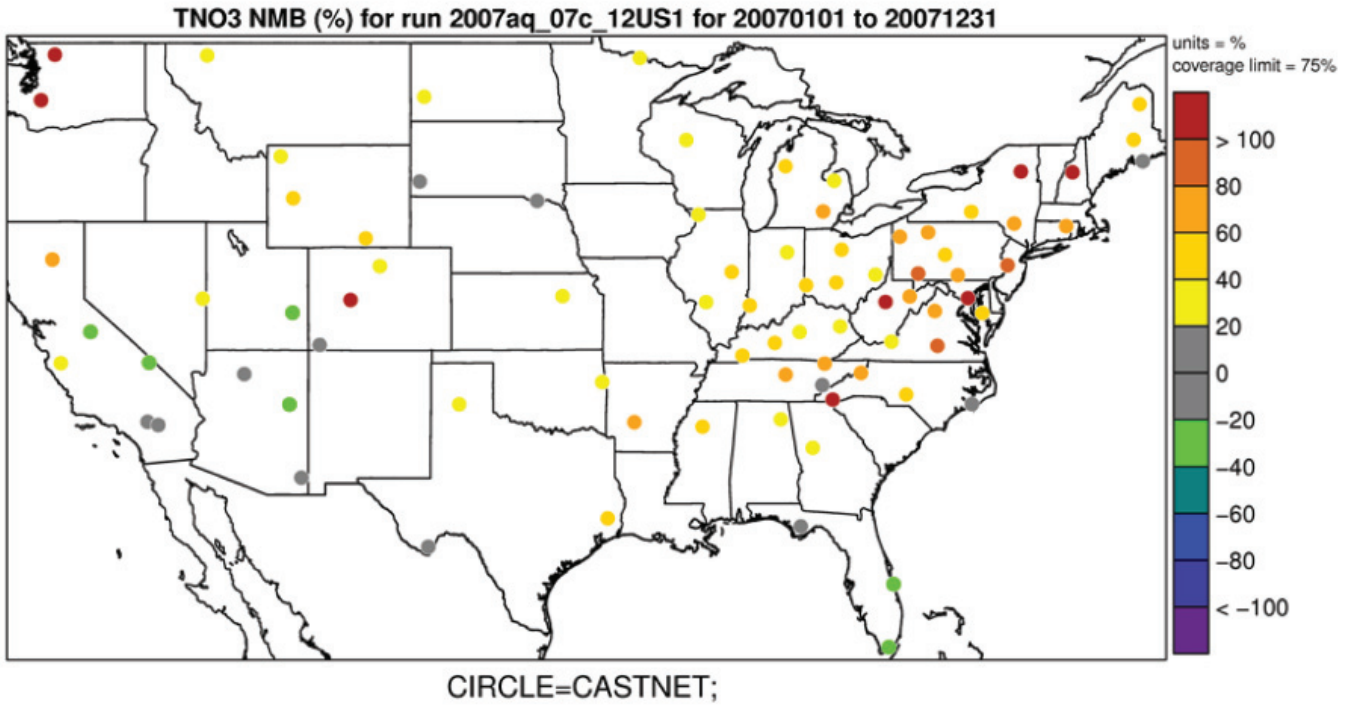

Figure 4-7. Normalized Mean Error (%) of annual Sulfate at monitoring sites in the continental U.S. modeling domain.

ranging from -0.4 to -10 percent). In contrast, the model tends to slightly under predict in the Southeast and Western states at CSN and CASTNet sites (NMB ranging from 5 to 18 percent). There is not a large variation from subregion to subregion or at urban versus rural sites in the error statistics for ammonium.

Annual average elemental carbon is under predicted in all subregions at urban sites with the exception of the slight over prediction in the Northeast. At rural sites, elemental carbon is over predicted in the Northeast, Central and West, although elemental carbon is under predicted in the Midwest and Southeast. Similar to ammonium error model performance, there is not a large variation from subregion to subregion or at urban versus rural sites.

Annual average organic carbon is under predicted in the Midwest, Southeast and Central states at the urban and rural monitoring sites. In contrast, organic carbon model bias tends to show a slight over prediction in the Northeast and West. Similar to ammonium and elemental carbon, error model performance does not show a large variation from subregion to subregion or at urban versus rural sites.

5.0
Bayesian Model-Derived Air Quality Estimates

5.1 Introduction

The need for improved spatial and temporal estimates of air quality has grown rapidly in recent years, as the development of more thorough air quality related health studies have begun requiring more thorough characterizations of ground-level air pollution levels. The most direct way to obtain accurate air quality information is from measurements made at surface monitoring stations across the country. However, many areas of the U.S. are not monitored and typically, air monitoring sites are sparsely and irregularly spaced over large areas. One way to address the limits to ambient air quality data is to combine air quality monitoring data and numerical model output in a scientifically coherent way for improved spatial and temporal predictions of air quality. This type of statistical modeling could provide spatial predictions over the temporal scales used to assess the associations between ambient air quality and public health outcomes and for assessing progress in air quality under new emission control programs. Hierarchical Bayesian Modeling (HBM) is used in numerous applications to combine different data sources with varying levels of uncertainty. This section will briefly introduce the Hierarchical-Bayesian approach developed by EPA for use in the EPHT program.

The approach discussed in this section combines the strength of both modeled and monitored pollution concentration values to characterize air quality with estimated accuracy and enhanced spatial and temporal coverage. The statistical approach is explained in McMillan, N., Holland, D.M., Morara, M, and Feng, J., "Combining Different Sources of Particulate Data Using Bayesian Space-Time Modeling," *Environmetrics*, **2010**, 21: pp 48—65, DOI: 10.1002/env.984.

5.2 Hierarchical Bayesian Space-Time Modeling System

5.2.1 Introduction to the Hierarchical-Bayesian Approach

EPA's Hierarchical-Bayesian (HB) space-time statistical model combines ambient air quality data from monitors with modeled CMAQ air quality output to produce daily predictions of pollution concentrations for defined time and space boundaries. Bayesian analysis decomposes a complex problem into appropriate linked stages (functions), i.e., a) air quality data; b) CMAQ model output; c) measurement errors and model bias; and d) the underlying 'true' concentration surface. A Bayesian approach incorporates 'prior knowledge' (e.g., numerical information describing known attributes/behaviors, statistical distributions, etc.) of the unknown parameters in the hierarchical model, which results in an improved estimation of the uncertainty of the 'true' air pollutant concentration at any location in space and time. A hierarchical model builds a combined solution, superior to either air quality monitor data or air quality modeling data alone.

The predictions of the ambient concentration 'surface' provided by EPA's HB Model are for a selected year and with spatial scope spanning across the contiguous U.S. (i.e., the 'lower 48' states). The HB Model methodology blends the best characteristics of monitored concentration values and modeled concentration values for prediction of the 'true' concentration values (surface) over time when both sources of data are available. Air quality monitors are assumed to measure the true pollutant concentration surface with some measurement error, but no bias. In contrast, numerical output from source-oriented air quality models is assumed to approximate the variability of the true surface while exhibiting both measurement error and bias (additive and multiplicative) across space and time. Given the typical exponentially distributed nature of air quality data, the HB Model performs its analysis with log-transformed monitoring and modeling inputs. The HB Model gives more weight to accurate monitoring data in areas where monitoring data exists, and relies on bias-adjusted model output in non-monitored areas. The HB Model approach offers the ability to predict important pollution gradients and uncertainties that might otherwise be unknown using interpolation results based solely on air quality monitoring data. EPA's HB Model can be used to obtain surrogate measures of air quality for studies addressing health outcomes.

5.2.2 Advantages and Limitations of the Hierarchical-Bayesian Approach

At a high level, the advantage of HB modeling methodology is its inherent ability to predict air quality estimates for selected times and spatial scales using air quality monitoring and air quality modeling data as input, while minimizing the limitations which arise when either of these methods are applied separately. Another important advantage of the HB modeling approach is the ability to predict estimates of errors in air quality. The HB modeling approach generates estimates of air quality for days when monitoring data is missing, in addition to estimating air quality in areas without monitors. An important disadvantage of HB modeling is the computational burden imposed on model users. Typically, these models are 'adjusted' by running numerous simulations, and at times the solutions are difficult to program and require significant computer resources. Thus, there is the need for EPA to develop an operational approach to HB modeling. It requires experience and statistical expertise to ensure

that proper (initial) modeling assumptions have been used, that proper convergence criteria have been used for the HB Model, and that the results are reasonable.

In setting up the procedures for developing the HB Model estimates, EPA selected a set of data quality objectives, DQOs, to guide the acceptance of the results. Based on an independent data set (not used in the predictions), EPA calculates (1) the *Bias* as the absolute difference between the (log-transformed) measurement generated from the monitor at that location (i.e., the "true" value) and the log-transformed prediction that is made by the particular model; and (2) the *Mean Square Error (MSE),* calculated as the square of the bias. EPA presents three different types of MSE summaries: (a) day-specific MSE, averaged over all monitoring locations; (b) location-specific MSE, averaged over all monitoring days; and (c) the overall MSE (i.e., averaged across locations and time). MSE is a statistical score that represents overall (average) performance in which large deviation from the "true" value yields larger penalties compared to small errors. While these performance measures were used in evaluating the results, they have no absolute acceptance/rejection values and are considered on a case-by-case basis when evaluating the performance of any years of HB Model application. In general, while the DQO's usefulness is still being studied and EPA attempts to achieve these DQOs, these measures are helpful at this time to describe the quality of the HB predictions from one model year to another.

In developing and providing the HB Model results, EPA is attempting to advance the use of improved air quality estimates. As such, the proper use of the EPA results is important and discussed further in Section 5.6.

5.3 Results for O_3 and $PM_{2.5}$

The HB Model yields a predicted daily concentration and error estimate for those predictions within each grid cell for each day within the time period of interest. The concentrations are daily $PM_{2.5}$ or 8-hour maximum ozone levels. These predictions fall along a smooth (congruent) response surface across the entire region. The grid used by the HB Model is the same as that used in generating the CMAQ estimates. The smoothness of the surface is achieved by: 1) the choice of prior distributions for air data, CMAQ output, and the true underlying predictive surface; and 2) the conditional autoregressive model (CAR) spatial covariance structure where a grid's predicted concentration is assumed to be correlated with neighboring cells (note the HB Model can handle different size neighborhoods). The resulting HB Model prediction surface approximates the true underlying response surface while accounting for such factors as measurement error and potential space-time bias in the CMAQ output.

EPA stores the set of back-transformed predictions (pm25_pred, O3_pred) and standard errors (pm25_stdd, O3_stdd) from a given execution of the HB Model in tabular (comma-delimited) format within a file named as in the following example: pm25_surface_12km_2007.csv. Table 5-1 presents an example of the output that can be obtained from this file. One row exists in this file for each grid cell-date combination within the study area. The relevant variables in this file, in the order in which they exist (and are portrayed within the column headings of the table), are as follows:

- Date: Represented by the data given in this row, in MM/DD/YYYY format.
- Longitude: The x-coordinate value transformed to longitude (degrees).
- Latitude: The y-coordinate value transformed to latitude (degrees).
- Column: The column associated with model results.
- Row: The row associated with model results.
- pm25_pred or O3_pred
- pm25_stdd or O3_stdd

5.4 Overview of HB Model Predictions

Below is a short description of the inputs and outputs for a HB Model application for 2007, 12 km grid, $PM_{2.5}$. A description of the input metadata and HB Model application can be found in Appendix E. The air quality data come from EPA AQS, the CMAQ was run by EPA as documented elsewhere in this report and the HB Model was applied at EPA's NERL. The domain of the CMAQ model (and therefore the HB Model predictions) is found in the following table.

Figure 5-1 shows the HB Model prediction for $PM_{2.5}$ during July 1-4, 2002. On July 1, the $PM_{2.5}$ levels were the highest along the U.S.-Canada border northeast of Lake Erie and into the mid- Atlantic region. As the days passed, the elevated $PM_{2.5}$ decreased in intensity and moved southeast. Examining the figure, it is possible to see the change in $PM_{2.5}$ level at any point in the domain. Figure 5-2 shows a close up of the HB Model predictions for July 2. The 12-km grid can be seen as small squares. Within each grid the predicted $PM_{2.5}$ concentrations are constant. As such, the $PM_{2.5}$ concentrations represent an average over the area where the public is exposed to ambient $PM_{2.5}$. Although actual concentrations within grid cells vary over space and time during a day, the ambient exposure is likely to be somewhat averaged as people move about within and between grid cells. Given the relationship between ambient concentrations, ambient exposures and personal exposure is not understood well, one area of study is the degree of misclassification between exposure and health outcomes based on varying grid sizes.

The HB Model results can track with the AQS data and CMAQ estimates and the predictions can differ from either the AQS data or the CMAQ estimates. Figure 5-3 shows HB predictions for a location where the predictions generally follow temporally the CMAQ and AQ data. This figure shows a series of days where AQS data and CMAQ estimates are fairly consistent. In such cases, the HB Model predictions track closely to both inputs. Figure 5-4 shows how the HB Model fills in $PM_{2.5}$ predictions for days when AQS data are not available (many $PM_{2.5}$ monitors are operational and

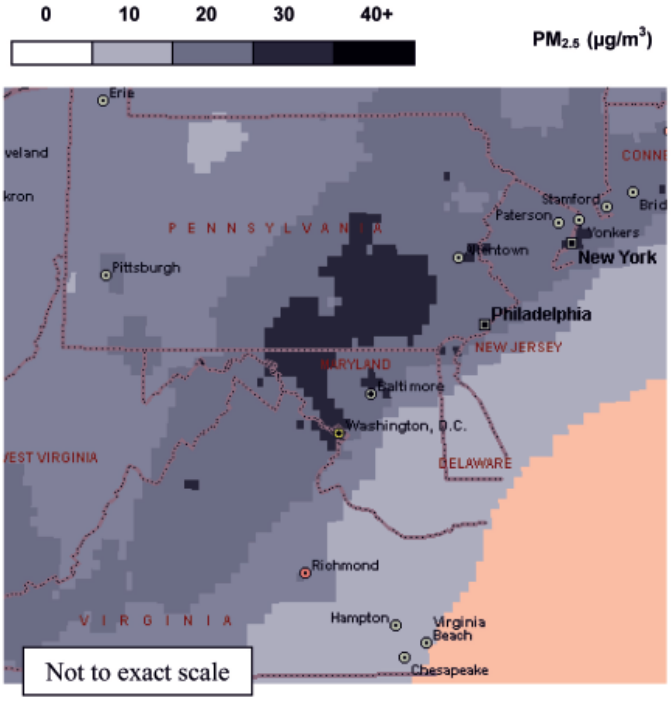

Figure 5-2. HB Prediction ($PM_{2.5}$) on July 2, 2002 (12 km grid cells)

collect samples during 1 day in every 3-day time period). On the unmonitored days, the HB Model predictions track well with the CMAQ estimates. Figure 5-5 shows a situation where AQS and CMAQ do not agree well and, while the HB Model tends to mitigate the bias of CMAQ, the HB Model the predictions can be highly affected by CMAQ, although

Another way to view the ability of the HB Model to fill in estimates of air quality where no monitor exists can be seen in the following figures. The HB Model response surface is plotted with the grid demarcations in Figure 5-6 along with the measurements taken at the monitoring stations. Figure 5-7 rotates this plot to portray its 3-dimensionality, so that differences between the HB Model predictions and the monitoring data points can be better seen. The view portrayed in Figure 5-7 is as seen from the position of the red arrow in Figure 5-6. As in the previous figures, different colors represent different concentration gradients (as noted within the legend included in the plot). These figures show how the HB Model prediction surface aligns closely with the monitoring station data in most instances, except for a cluster of data points in the upper center of the plot. Figure 5-8 portrays the same plot as Figure 5-6, but with the CMAQ-estimated $PM_{2.5}$ surface added. The CMAQ surface features have more yellow shading within them, implying that the CMAQ concentration values somewhat underestimate the concentrations relative to the HB Model and the monitoring stations. However, in areas in which there are few or no monitoring stations, the HB Model surface corresponds closely with the CMAQ surface. This is to be expected, as the HB Model weighs (uses a bias adjustment of) the CMAQ data more heavily in areas without monitoring data.

Figure 5-9 displays the ozone concentration for the continental U.S. on July 26, 2005. The spheres represent the concentrations recorded at monitor locations. The green, blue, and yellow represent the HB concentration surface, which combines the CMAQ model estimates and the $PM_{2.5}$ monitor measurements.

5.5 Evaluation of HB Model Estimates

As reported in the McMillan paper (*Environmetrics*, 2010), model validation analysis was performed to compare the HB predictive results at 2001 STN/IMPROVE monitoring sites to predictions at those locations from two other approaches: (1) traditional kriging predictions based solely on the FRM monitoring data and (2) CMAQ output at these locations. In doing so, it was assumed the STN/IMPROVE measurements represent the "truth." The IMPROVE measurements are representative of rural areas (with few monitors) and may help assess the HBM results for these areas of interest. The potential bias in either the STN or IMPROVE gravimetric mass measurements compared to FRM data were not considered, although for gravimetric mass the monitors generally produce the same results. STN data collocated with FRM monitoring sites used in fitting the HB Model were eliminated from the validation data set, leaving 44 sites for the validation analysis.

In the validation analysis, mean squared prediction error and bias were calculated to evaluate the predictive capability of these three different models. To assess the ability of the HB Model to accurately characterize prediction uncertainty, the percentage of validation data within the 95 percent prediction credible interval was calculated. In the analysis, a similar analysis was performed for the kriging model by calculating 95 percent confidence intervals at the validation sites. An exponential variogram model was used for the kriging model. The exponential parameters were estimated by fitting this model to an empirical variogram based on combining the daily empirical variograms.

In this analysis, predictions for each day were obtained for the STN/IMPROVE site locations from the three modeling approaches and the validations statistics were calculated across all days and sites. The validation only occurs every third day, according to the sampling schedule of STN/IMPROVE. This corresponds to the full network FRM schedule. Thus, the analysis did not evaluate sparse monitoring days where data fusion is expected to outperform interpolation techniques based solely on the monitoring data.

In the analysis, the HBM was run several times using a range of reasonable priors. Then, the validation analysis assessed the relative predictive performance of the HBM, traditional kriging, and CMAQ as described above. In terms of mean squared prediction error (MSE), the HBM and kriging approaches provided similar results across all HBM runs. For bias, the HBM outperformed kriging by 10 to 15 percent depending on the prior assumptions for τ^X and τ^Y. CMAQ was nearly unbiased for this analysis.

Kriging uncertainties were reflected in the small percentage (59%) of kriging prediction intervals capturing the validation data. This compares to HBM predictive interval results of 80

to 90 percent depending on the HBM run. This occurs from the difference between the HBM results and the 95 percent nominal rate to the difference in the measurement errors in the validation to those in the FRM data used in fitting the HBM model. Unfortunately, error-free $PM_{2.5}$ monitoring data are not available with current $PM_{2.5}$ monitoring approaches.

5.6 Use of EPA HB Model Predictions

Over the next several years, NERL will be working to improve spatial and temporal estimates of ambient pollutant concentrations to facilitate improved modeling of human exposure. The goal is to improve exposure modeling for intracity and intercity exposure comparisons and to develop better understood exposure surrogates for use in air pollution health studies. Given the uncertain characterization of air quality, especially at locations at a distance from central monitoring sites, NERL has been working to develop the HB Model (and other approaches) for estimating ambient and exposure concentrations for use in health studies, benefits assessments, and other air program analyses.

The HB Model as developed by NERL is part of a continuing research program. Accordingly, it should be understood by users of the HB predictions that the underlying statistical model is continuing to be studied and improved. However, given the uncertain nature of air quality, especially at locations well-removed from monitoring sites, NERL has been working to develop the HB Model (and other approaches) for estimating ambient and exposure concentrations for use in health studies, benefits assessments, and other air program analyses. To encourage assessments of these predictions from the HB Model, NERL is making the predictions available based on a general DQO approach of determining whether the predictions from the HB Model are appropriate for use for these purposes. This approach allows use of uncertain results by providing the statistical error estimates for the predictions and an assessment of the predictions. In this manner, users can assess the effects of the uncertainty for the predictions with their studies.

Based on NERL's current model evaluation results, the HB Model predictions provide credible predictive surfaces of air quality (ozone and $PM_{2.5}$), in particular away from monitoring sites. The HB Model, as initially configured, predicts to the central tendency with the potential distributions (that is, each estimate represents a mean value from the distribution of possible values for each space-time point). This means that the HB Model will tend to under-predict very high values (the implications of this are being investigated). Nevertheless, the HB predictions, by "filling-in" pollutant concentration values for missing (non-monitored) locations and missing (unsampled) days of air quality estimates, are likely to be an improvement compared to simply using the monitoring results. In addition, as the HB Model is a space-time model, it is more credible than statistical interpolation of the monitoring data where there are missing monitoring data (this is the predominate issue for 1 in 3 day $PM_{2.5}$ monitoring sites across the U.S.). The HB Model, and other statistical methods, is more scientifically credible than simple mathematical techniques, such as inverse distance weighting.

Given the uncertainty and the complexity of using the HB Model predictions, careful use of the HB predictions is needed. Until a thorough study of several prediction years and scales (grid sizes) is completed, the results should be used by professionals with an ability to understand anomalous outcomes when using the predictions in a health study. An exception-based review of the HB predictions should be undertaken by each researcher, in the context of a study's data needs, to ensure "outliers" do not influence subsequent analyses. The HB predictions include a few very high values which cannot be rejected out-of-hand without further study. Studies of the representativeness of the HB Model predictions and additional experience with the prediction will provide a better understanding of the limits of using these predictions. The HB Model was initially designed for use as a source of air quality estimates in case-crossover analyses where temporal and spatial variability was needed. The predictions could be used within the EPHT program in health surveillance activities, to generate hypotheses for further studies, and as a basis for indicators in counties without monitors. They also can be used in Health Impact Assessments in place of interpolated monitoring data.

EPA continues to research approaches to combining air quality data and model results to predict statistically air quality estimates for use in health studies and elsewhere in the air program. There are key scientific questions that the HB Model (and other techniques) may help address. For example, determining the most representative scale (12 km or smaller scale) of ambient air quality measures (as surrogate for ambient exposure or personal exposure) for use in associating health outcome data with air quality changes needs to be better understood. The effect of (monitor) measurement variability and CMAQ bias on the usefulness of the HB predictions is also an important aspect for further improvement of air quality measures used in health studies.

Table B-18i: Column Merge Grid Emissions [to obtain domain totals]

Appendix C
Metadata

Output Data

The pm25_surface_12km_2007.csv (or o3_surface_12km_2007.csv) file is the output file from EPA's Hierarchical Bayesian Model (HBM) that combines $PM_{2.5}$ (or O_3) monitoring data from National Air Monitoring Stations/State and Local Air Monitoring Stations (NAMS/SLAMS) and Models-3/Community Multiscale Air Quality (CMAQ) computer-simulated $PM_{2.5}$ or O_3 data. This file provides a spatial interpolation of air quality that takes advantage of the strengths of monitoring network observations and modeling estimates to generate daily surrogate measures for $PM_{2.5}$ and relates these measures to available public health data. The file covers the contiguous lower 48 states of the United States. The time frame covered is January 1, 2007 through December 31, 2007. The standard errors of the estimates should be taken in to account when using the results. This file is a comma-separated values (CSV) file. This is a flat file that is platform-independent. In the Microsoft Windows computing environment, this file can be read easily by Excel.

The file contains the posterior means and standard errors of the estimated space-time surface, the posterior means and standard errors of the estimated space-time bias surface, and the posterior means and standard errors for a surface made up of 12 km x 12 km contiguous grids. The contiguous 12 km x 12 km grids cover the whole lower 48 contiguous states of the United States. The file includes the following variables: Date, Latitude, Longitude, posterior mean estimated $PM_{2.5}$ or O_3 concentration on natural log scale (PredAvg), row position of grid cell, column position of grid cell, standard error of the estimated $PM_{2.5}$ or O_3 concentration on the natural log scale (PredStd), the natural log of the estimated CMAQ model data bias (Bias), and the standard error of the estimated CMAQ model data bias (BiasStd). Values of -999 in the data set represent missing (or intentionally excluded) values. Excluded values are generated when grid cells are not included in the model calculation. These are not actual missing values but intentionally not included in the grid for calculation of the estimated surface. An example of such a grid cell not included is grid cells that fall over water.

Input Data

The actual monitoring data from the NAMS/SLAMS network were downloaded from the Air Quality System (AQS) database. Only Federal Reference Method (FRM) samplers and only those samplers with sample duration of one day (24-hour integrated sample) were included in the data set.

The CMAQ data was created from version 4.7 (4.7.1) of the model which includes improved aqueous chemistry and photolysis mechanisms. The $PM_{2.5}$ data is a 24-hour integrated $PM_{2.5}$ concentration calculated on a 12-km x 12- km grid for the entire United States. These CMAQ results are based on emission inputs for the 2005v4 Platform from the 2005 National Emission Inventory (NEI), Version 2, which includes emissions of CO, NO_x, VOC, SO_2, NH_3, PM_{10}, and $PM_{2.5}$ and hazardous air pollutants (HAPs), including chlorine, HCl, benzene, acetaldehyde, formaldehyde, and methanol. In addition, the meteorological data used for these model results is from the Weather Research and Forecasting Model (WRF) version 3.1 simulations (Advanced Research WRF [ARW] core).

The HBM combines the actual monitoring data (NAMS/SLAMS), the estimated $PM_{2.5}$ or O_3 concentration surface (CMAQ), and the prediction of $PM_{2.5}$ or O_3 through space and time. The model assumes that both the actual monitoring data and the CMAQ data provide good information about the same underlying pollutant surface, but with different measurement error structures. It gives more weight to the accurate monitoring data in areas where monitoring data exists and relies on the CMAQ data and satellite data in areas where no monitoring data is available. The modeling is divided into hierarchical components where each level of the hierarchy is modeled conditional on the preceding levels. To fit the model, a custom-designed Monte Carlo Markov Chain (MCMC) software algorithm was used. Model-specific input parameters of statistical distributions for the model and simulation parameters (priors) are specified for each run of the model. The projections for the grid cell structure are as follows:

Projection: Lambert conformal with spherical earth, radius = 6370.0 km

12-km Resolution

NCOLS = 459

NROWS = 299

P_ALP = 33.00

P_BET = 45.00

P_GAM = -97.00

XCENT = -97.00

YCENT = 40.00

XORIG = -2556000.0

YORIG = -1728000.0

XCELL = 12000.00

YCELL = 12000.00

These values are for the 12-km grid resolution of CMAQ.

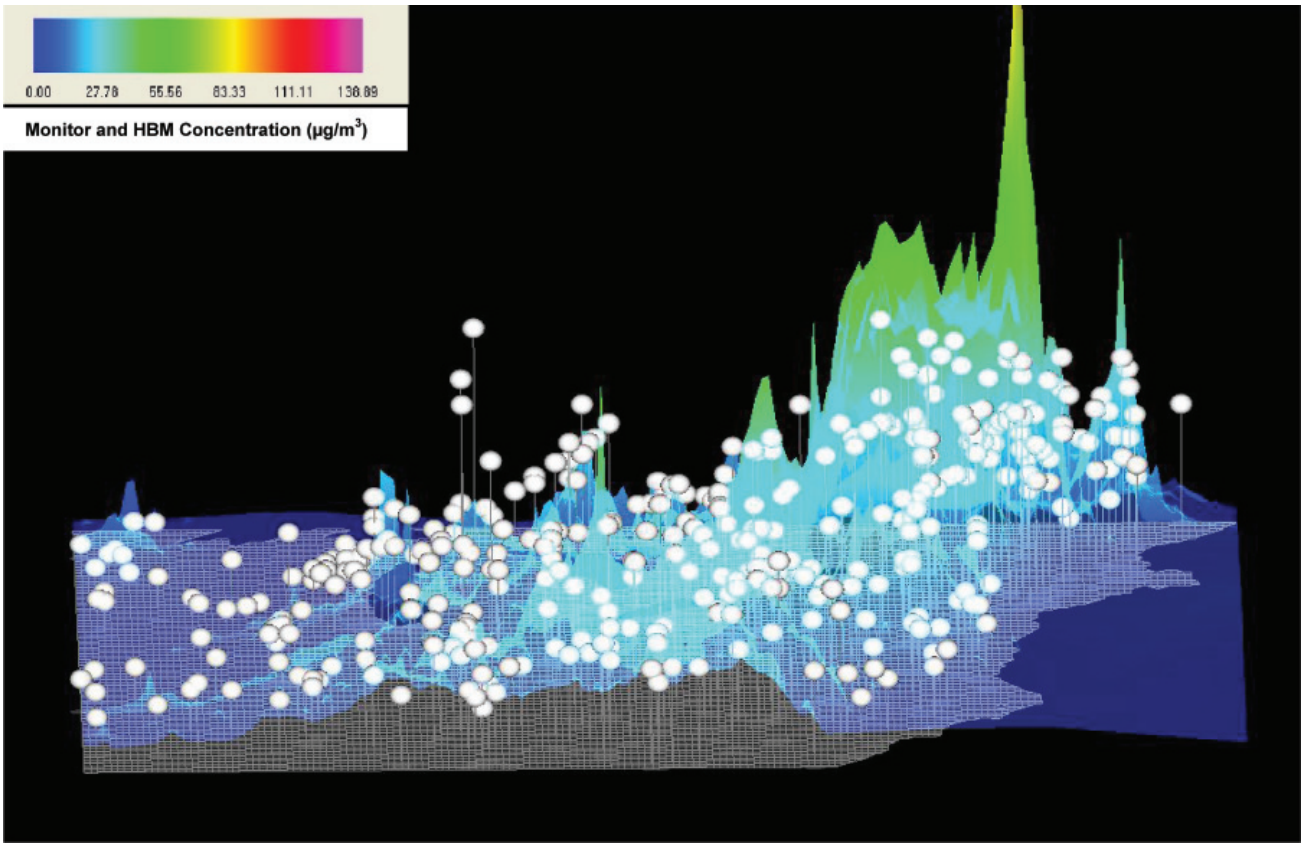

Figure C-1. $PM_{2.5}$ Monitoring Data and CMAQ Surface (Separately Displayed—White Spheres Represent Monitor Locations and Associated Concentration Values)

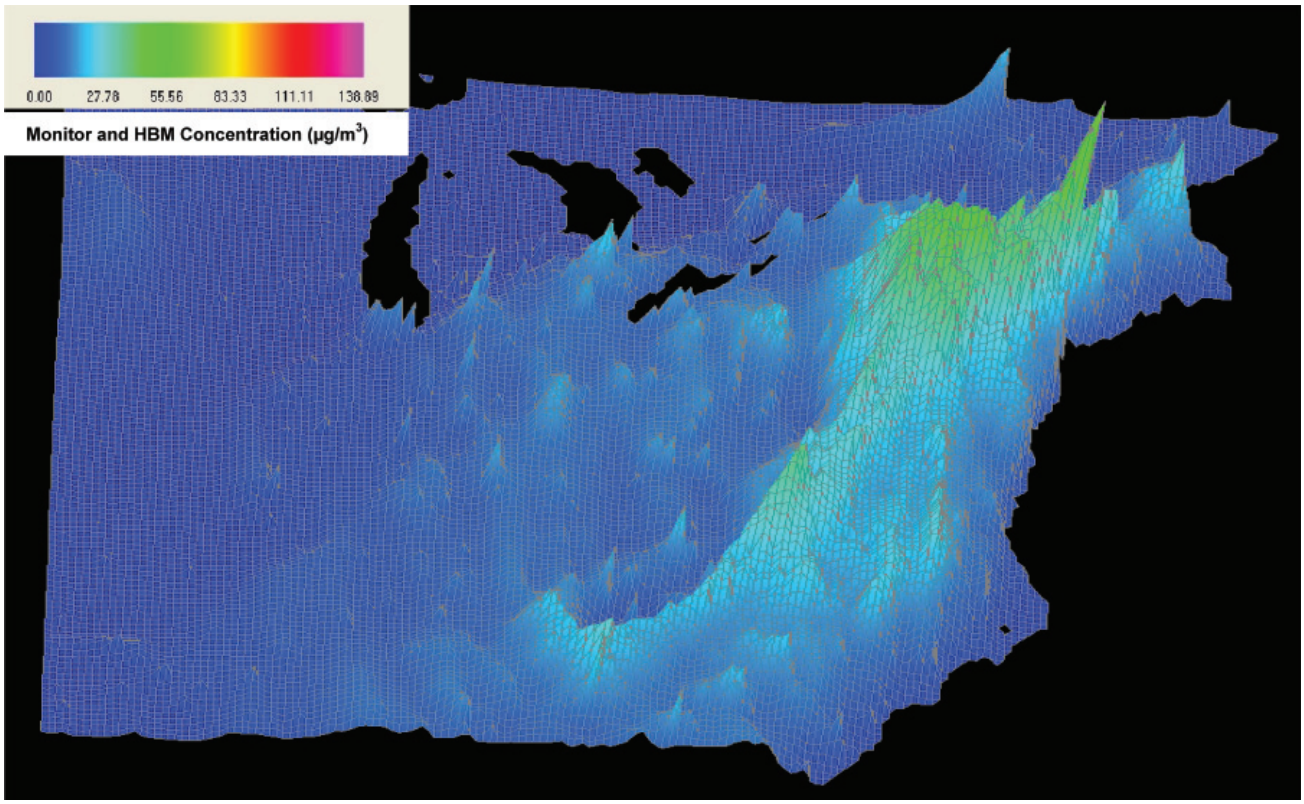

Figure C-2. Combined $PM_{2.5}$ Monitoring Data and CMAQ Surface (Via HBM)

The geographic boundaries of the HB output cover the following region:

111.1 degrees W longitude—West Bounding Coordinate

65.4 degrees W longitude—East Bounding Coordinate

51.25 degrees N latitude—North Bounding Coordinate

23.0 degrees N latitude—South Bounding Coordinate

The definitions for the 12-km x 12-km CMAQ grid cells are contained in a text (*.txt) file. The file contains the latitude and longitude coordinates of the following points for each grid cell: 1) center; 2) southwest corner; 3) southeast corner; 4) northwest corner; and 5) northeast corner. The AQS data for $PM_{2.5}$ and O_3 are contained in separate text (*.txt) files. These files contain the following data: parameter occurrence code (for pollutant); state code; city code; site ID; sampling frequency; data; sample value; monitor protocol (i.e., 1 in 3 days); partition, etc. Example figures of a) a separate air quality monitor with CMAQ data, and b) combined air quality monitor data and CMAQ data for $PM_{2.5}$ are shown below.

Use of HB Data to Generate Health Indicators

The HB output data can be used to generate health (air) indicators which are useful to researchers when developing health impact assessments (HIA). The HB output is provided in a gridded (x-y/row-column) format and that format must be translated to different coordinate systems (e.g., county-based/relevant coordinates) to provide health indicator data for the area(s) of interest. An important coordinate projection system used as a standard coordinate representation format to express different location designation systems in consistent terms is the Lambert Conformal Conic (LCC) projection coordinate system. The North American Datum (NAD) geodetic system describes the Earth's ellipsoid based on the latitude and longitude location of an initial point, and serves as the basis of maps and surveys of the Earth's surface. The NAD-27 datum is based on the Clarke Ellipsoid (Earth spheroid) of 1866 and is centered at a base station on the Meades Ranch in Kansas. The NAD-83 grid projection/ datum is based on the Geodetic Reference Spheroid (GRS) of 1980 and is geocentric (e.g., based on the Earth's center with no directionality or initial point located on the Earth's surface). The NAD coordinate system is important because health-related data (used to calculate health indicators) are collected and cataloged based on this coordinate system (e.g., U.S. Census data is based on NAD-83 coordinates).

The HB output provides ambient concentration data for both ozone and fine particulate matter in x-y-based grid cells, and to correlate this concentration data with health data, the x-y locations must be 'mapped' to latitude/longitude locations and then mapped to the correct datum/projection system linked with the health data. The typical latitude and longitude grids are based on the World Geodetic System (WGS) projection for 1984 (WGS-84), while the U.S. Census uses the NAD-83 grid and the SAS statistical analysis software uses NAD-83 grid projection. When generating the linkage between the ambient concentration data and the health data, a methodology or protocol must be developed to relate the appropriate coordinate system/geocoding information between them.

CDC, EPA, and the state departments of air and/or health of New York, New Jersey, Massachusetts, and Minnesota have developed an initial set of health indicators using the HB output data correlated with available health data/ information. They have developed a 'relationship file' to map the x-y-based grid cells to latitude/longitude format with the appropriate datum/projection system(s). Shapefile information also resides in this file allowing compatibility with GIS map formats/applications. The relationship file has a grid ID, representing the row and column of the grid cell. This grid ID is a six-digit identifier from the HB raw data set that concatenates column and row designation. There are 66,000 grid cells per day times 365 days worth of data (the New York State Health Department uses SAS to process this data and CDC uses ArcGIS to process the data). The relationship file recognizes the importance of having consistent geocoding data for HB grids for Health Impact Analyses (HIA). The U.S. Census files (TIGER2000 files) are in NAD-83 format, which is what the SAS statistical software processes. The WGS-84 format is almost exactly like NAD-83 format except there is an offset of a few feet for grid points (centroids). WGS-84 is used by the CMAQ air quality model. Air Quality models such as CMAQ, which serve as input to the HB model, uses the meteorological software MM5 which is based on the Lambert Conformal Conic (LCC) projection. As long as the HB output data (latitude and longitude grid coordinates) can be mapped to the NAD-83 or NAD-84 (WGS-84) to match census data, air indicators can be generated for HIA. The x and y coordinates given in the HB are used to plot the latitude and longitude with an offset to match non-NAD-83 grid references. When defining Earth points, coordinate information should be modified into a format compatible with county-based maps and transformed into an elliptical projection. NetCDF file can be converted in ArcGIS to make shape files. The New Jersey state air department used the Theissen Polygon tool on HB data to generate shapefiles.

<u>How CMAQ and HB x-y grid locations are transformed to latitude and longitude values:</u>

There is an IOAPI file providing rows/columns, cell height/ width, origin in LCC, offset by ½ cell width/height to get center cell (centroid). Conversion uses an LCC routine in IOAPI library, passing parameters (Earth radius, central meridian [longitude: -97 degrees]), two key latitude values 33 degrees and 45 degrees, central meridian, -97 and latitude of origin, 40.0. These arguments are required for the LCC routine, which returns latitude and longitude. The code for transforming an LCC projection (e.g., CMAQ and HB Model x-y grid coordinates) to latitude and longitude values:

LCPGEO Fortran Code—LCC Conversion Program

****

Fortran Code for converting Lambert Conformal Conic to geodetic (lat/lon):

```
      subroutine lcpgeo(iway,phic,xlonc,truelat1,truelat2,xloc,
      yloc, & xlon,ylat)
c     write(*,*)'INCALL:',phic,xlonc,truelat1,truelat2
c
c     LCPGEO performs Lambert Conformal to geodetic
      (lat/lon) translation
c
c     Code based on the TERRAIN preprocessor for MM5
      v2.0, developed by Yong-Run Guo and Sue Chen,
      National Center for Atmospheric Research, and
      Pennsylvania State University
      10/21/1993
c
c     Input arguments:
c     iway        Conversion type
c                 0 = geodetic to Lambert Conformal
c                 1 = Lambert Conformal to geodetic
c     phic        Central latitude (deg, neg for southern hem)
c     xlonc       Central longitude (deg, neg for western hem)
c     truelat1    First true latitude (deg, neg for southern hem)
c     truelat2    Second true latitude (deg, neg for southern
                  hem)
c     xloc/yloc   Projection coordinates (km)
c     xlon/ylat   Longitude/Latitude (deg)
c
c     Output arguments:
c     xloc/yloc   Projection coordinates (km)
c     xlon/ylat   Longitude/Latitude (deg)

Coordinate Information

COORD-NAME	COORDTYPE	P_ALP	P_BET	P_GAM	XCENT	YCENT
'LAM_40N97W'	2	33.000	45.000	-97.000	-97.000	40.000

Grid Information

GRID-NAME	COORD-NAME	XORIG (m)	YORIG (m)	XCELL (m)	YCELL (m)	NCOLS	NROWS	NTHIK
12US1	'LAM_40N97W'	-1008000	-1620000	12000	12000	279	240	1

P_ALP = "PROJ_ALPHA"
P_BET = "PROJ_BETA"
LAMGRD3 = P_ALP <= P_BET. These are the two latitudes which determine the projection cone.
P_GAM = the central meridian
XCENT, **YCENT** = lat/lon coordinates for the center (0, 0) of the Cartesian coordinate system.
X_ORIG is the X coordinate of the grid origin (lower left corner of the cell at column=row=1), given in map projection units (meters, except in Lat-Lon coordinate systems).
Y_ORIG is the Y coordinate of the grid origin (lower left corner of the cell at column=row=1), given in map projection units (meters, except in Lat-Lon coordinate systems).
X_CELL is the cell dimension parallel to the X coordinate axis, given in map projection units (meters, except for Lat-Lon coordinate systems).
Y_CELL is the cell dimension parallel to the Y coordinate axis, given in map projection units (meters, except for Lat-Lon coordinate systems).
NCOLS is the number of columns (dimensionality in the X direction).
NROWS is the number of rows (dimensionality in the Y direction).
NTHIK is the thickness (number) of cells on the boundary domain required to accurately describe boundary mass flux (e.g., CMAQ uses NTHIK = 1)

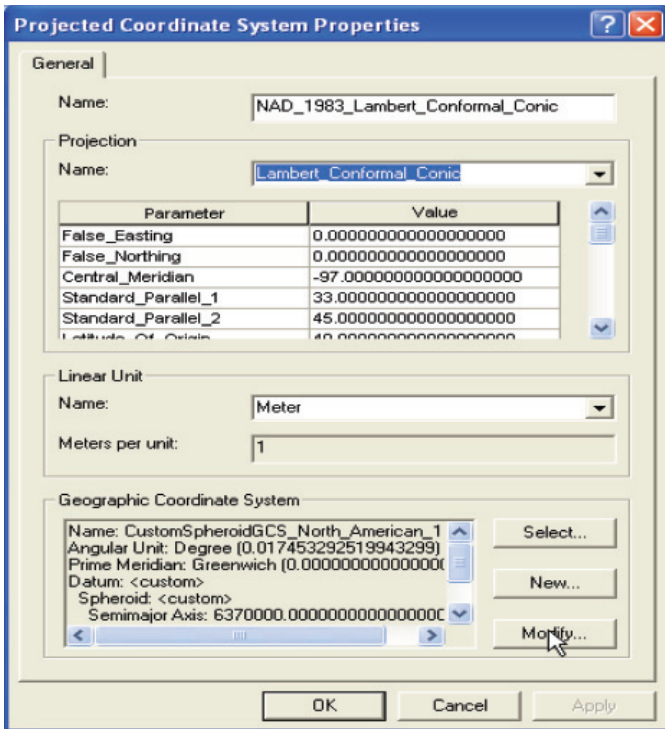
ArcMap Projection Information (HB grid example):

Data Type: File Geodatabase Feature Class
Location: U:\Projects\MMc-courtney\Grids\templates\grid_templates.gdb
Feature Class: template_mdhi_12_nb
Feature Type: Simple
Geometry Type: Polygon
Projected Coordinate System: NAD_1983_Lambert_Conformal_Conic
Projection: Lambert_Conformal_Conic
False_Easting: 0.00000000
False_Northing: 0.00000000
Central_Meridian: -97.00000000
Standard_Parallel_1: 33.00000000
Standard_Parallel_2: 45.00000000
Latitude_Of_Origin: 40.00000000
Linear Unit: Meter
Geographic Coordinate System: Custom-SpheroidGCS_North_American_1983
Datum: <custom>
Prime Meridian: Greenwich
Angular Unit: Degree

Changing a data set's spheroid to a sphere.

1) In ArcCatalog, right click the data set of interest, and choose **Properties**. Click the **XY Coordinate System** tab. Click Modify…

2) From the Geographic Coordinate System of the Projected Coordinate System Properties window, click Modify…



3) From the Geographic Coordinate System window, first choose <custom> in the list of datum (it's at the top) and then choose <custom> for the spheroid. Enter 6370000 in both the semimajor and semiminor boxes.
